# **Preface**

This book is a practical book to get started with C language. It describes all the elements of the language and illustrates their use with code examples.

Agus Kurniawan

Depok, March 2015

# **1. Development Environment**

This chapter explains how to start with development environment using C.

## 1.1 Getting Started

C is a general-purpose, imperative computer programming language. It supports structured programming, lexical variable scope and recursion, while a static type system prevents many unintended operations.

In this chapter, we prepare development environment to develop C program. You can write C program with your program. We focus on Windows, Linux and Mac platforms.

## 1.2 Compilers

There are many C compilers to develop C program. In this book, we use **GCC** as C compiler for Linux, Mac and Windows. For Windows users, you also can use Visual C++ compiler.

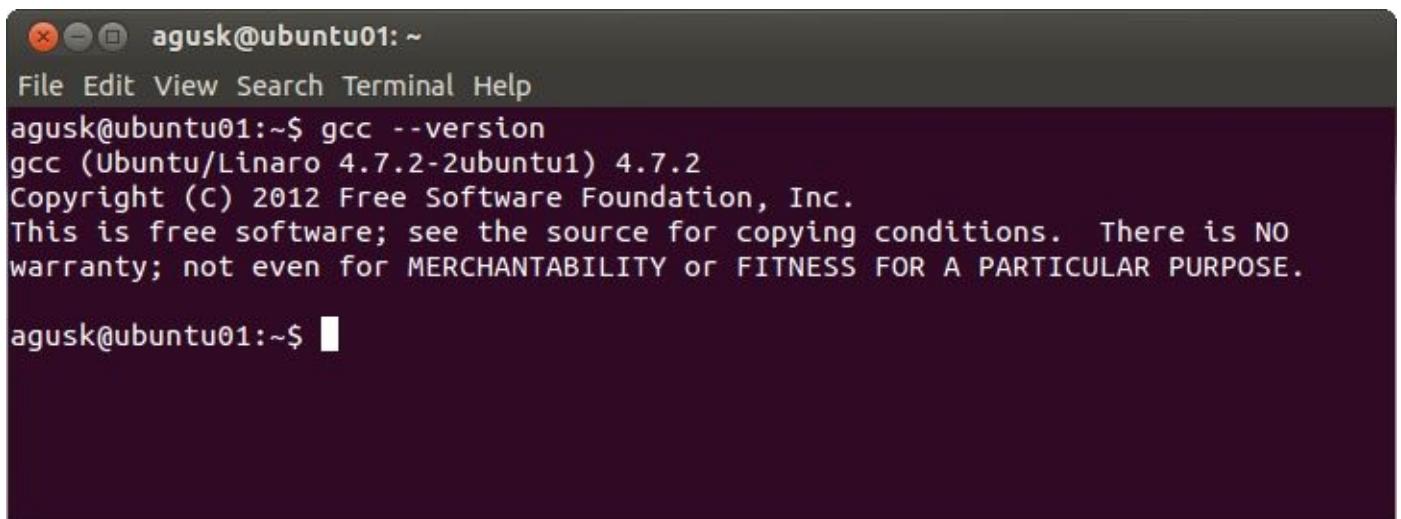

### 1.2.1 Linux

Installation of GCC C is easy. For Ubuntu Linux, you can do it using console and write this script

```
$ sudo apt-get install build-essential
```

If installation already finished, you can check GCC version on console and write script as below

```
gcc --version
```

The screenshot shows a terminal window with a dark background and light-colored text. The title bar says "agusk@ubuntu01: ~". The menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". The command "gcc --version" is entered at the prompt, and the output shows the version of the compiler installed on the system. The output is as follows:

```
File Edit View Search Terminal Help
agusk@ubuntu01:~$ gcc --version
gcc (Ubuntu/Linaro 4.7.2-2ubuntu1) 4.7.2
Copyright (C) 2012 Free Software Foundation, Inc.
This is free software; see the source for copying conditions. There is NO
warranty; not even for MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.

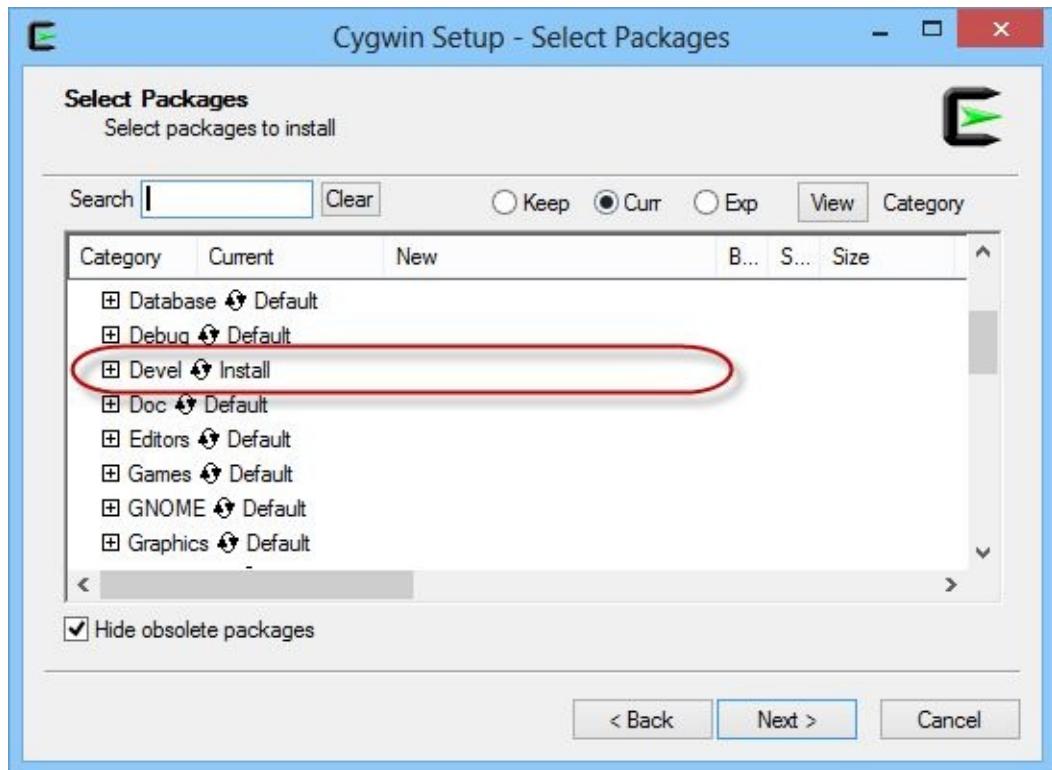

agusk@ubuntu01:~$
```

You will see gcc version, for instance shown in Figure above.

### 1.2.2 Windows

If your computer has Windows platform, you can use **Cygwin**. Download it on <http://cygwin.com/setup.exe> and then run it.

On setup dialog, you choose **Devel** package as follows.

After installed, you will get Cygwin terminal. Run it.

You can check GCC version. The following is a sample of output for GCC version

A screenshot of a Cygwin terminal window. The title bar says "Cygwin". The terminal prompt is "Agus@AKUR ~". The user types "\$ gcc --version" and the output is: "gcc (GCC) 4.5.3 Copyright (C) 2010 Free Software Foundation, Inc. This is free software; see the source for copying conditions. There is NO warranty; not even for MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE." The terminal prompt then changes to "\$ |".

## 1.2.3 Mac

To install GCC, you can install Xcode so you get GCC. After installed, you can verify it by checking GCC version.

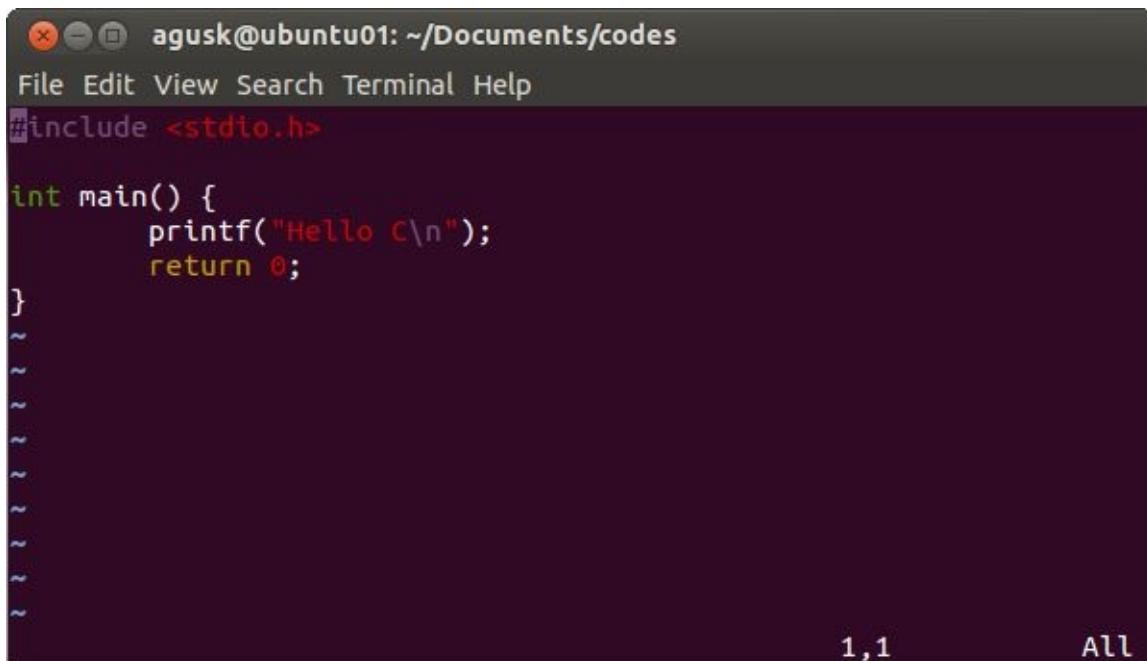

src — bash — 80x12

```
agusk$ gcc --version
Configured with: --prefix=/Applications/Xcode.app/Contents/Developer/usr --with-
gxx-include-dir=/Applications/Xcode.app/Contents/Developer/Platforms/MacOSX plat-
form/Developer/SDKs/MacOSX10.10.sdk/usr/include/c++/4.2.1
Apple LLVM version 6.0 (clang-600.0.57) (based on LLVM 3.5svn)
Target: x86_64-apple-darwin14.0.0
Thread model: posix
agusk$
```

### 1.3 Development Tools

Basically you can use any editor tool for instance, vi, vim, gedit, Eclipse. The following is vi editor in Ubuntu.

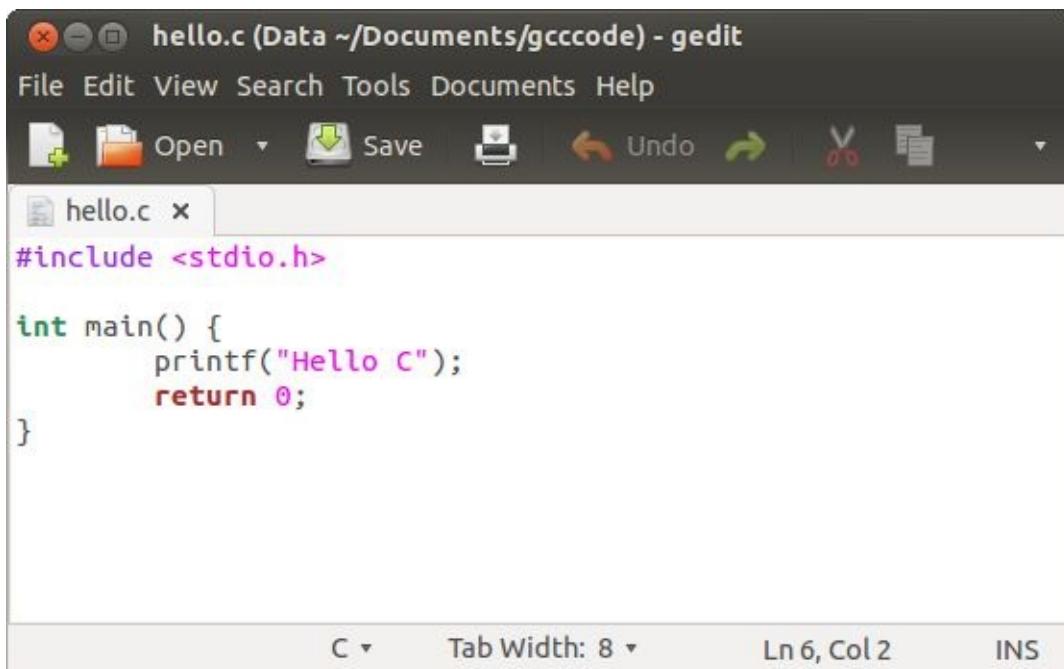

The screenshot shows a terminal window titled "agusk@ubuntu01: ~/Documents/codes". The window contains a vi editor session with the following code:

```
#include <stdio.h>

int main() {
    printf("Hello C\n");
    return 0;
}
```

The status bar at the bottom right shows "1,1" and "All".

Here is gedit editor

The screenshot shows a gedit application window titled "hello.c (Data ~/Documents/gcccode) - gedit". The window contains the following C code:

```
#include <stdio.h>

int main() {
    printf("Hello C");
    return 0;
}
```

The status bar at the bottom right shows "C", "Tab Width: 8", "Ln 6, Col 2", and "INS".

## 1.4 Hello World

Now we start to write the first program using C.

Firstly, open your text editor and create new file, called **hello.c**

Let's write this code

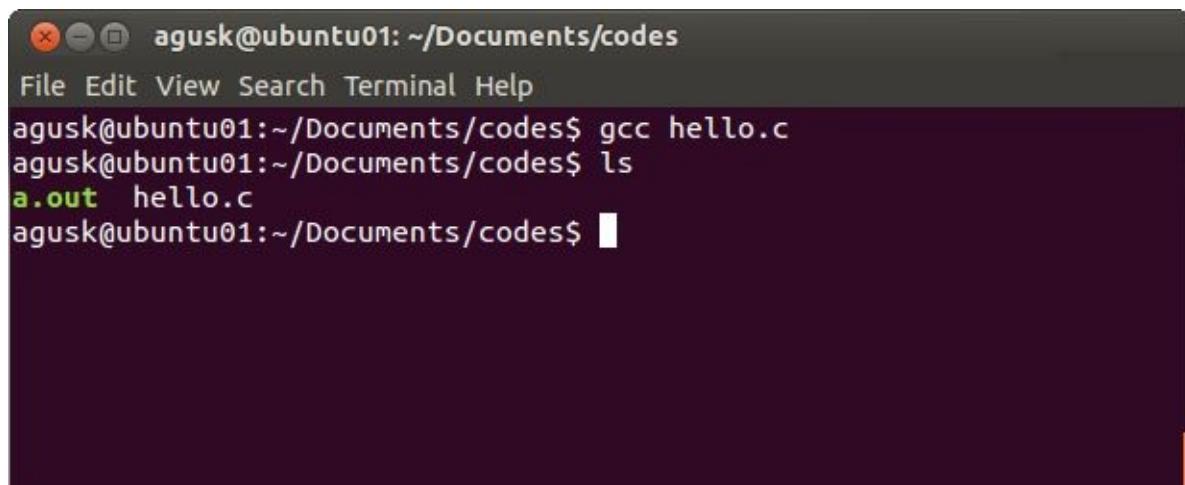

```
#include <stdio.h>

int main() {
    printf("Hello C\n");
    return 0;
}
```

Save this file.

Now open your Terminal and compile this file.

```
sudo gcc hello.c
```

The screenshot shows a terminal window with a dark background and light-colored text. The window title is "agusk@ubuntu01: ~/Documents/codes". The terminal prompt is "agusk@ubuntu01:~/Documents/codes\$". The user runs the command "gcc hello.c", which compiles the source code. Then, the user runs "ls" to list the files in the directory, showing "a.out" and "hello.c". The terminal ends with the prompt "agusk@ubuntu01:~/Documents/codes\$".

If you check, you will get file **a.out**. GCC will generate a.out file if you don't specify an output file name. You can define the output compiled file as follows

```
sudo gcc hello.c -o hello
```

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc hello.c
agusk@ubuntu01:~/Documents/codes$ ls
a.out hello.c
agusk@ubuntu01:~/Documents/codes$ gcc hello.c -o hello
agusk@ubuntu01:~/Documents/codes$ ls
a.out hello hello.c
agusk@ubuntu01:~/Documents/codes$
```

After compiled, you can run the compiled file by writing this command (for instance, the compiled file is hello.out)

```
./hello
```

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ ./hello
Hello C
agusk@ubuntu01:~/Documents/codes$
```

A sample output of program is run on Mac platform.

```
src — bash — 80x12
agusk$ ls
address.c      dpointer.c    hello.c        logical.c      refpointer.c
arith.c        dtwopointer.c  ifdemo.c      mathdemo.c    structdemo.c
arraydemo.c    for.c         incdec.c     multiarray.c  switch.c
comp.c         funcdemo.c   inout.c       pointer.c    while.c
agusk$ gcc -o hello hello.c
agusk$ ./hello
Hello C
agusk$
```

## **2. Basic C Programming Language**

This chapter explains the basic of C programming language.

## 2.1 Common Rule

In C language if you write a line of code we must write semicolon (;) at the end of code.  
Here is the syntax rule:

```
syntax_code;
```

## 2.2 Declaring Variable

To declare a variable called *myvar1*, write the following:

```
int myvar1;
```

**int** is data type.

The following is the list of common data type you can use in C language.

- int
- long
- float
- char
- double

We can also write many variables as follows:

```
int myvar1, myvar2;
```

Once declared, these variables can be used to store data based on its data type.

## 2.3 Assigning Variables

Variable that you already declare can be assigned by a value. It can be done using the equals sign (=). For example, variable **myvar1** will assign the number 100, you would write this:

```
int myvar1 = 100;
```

You also declare as below

```
int myvar1;
myvar1 = 100;
```

You must assign a value on a variable properly based on data type. If not, you will get error on compiling process, for instance, write this code

```
#include <stdio.h>

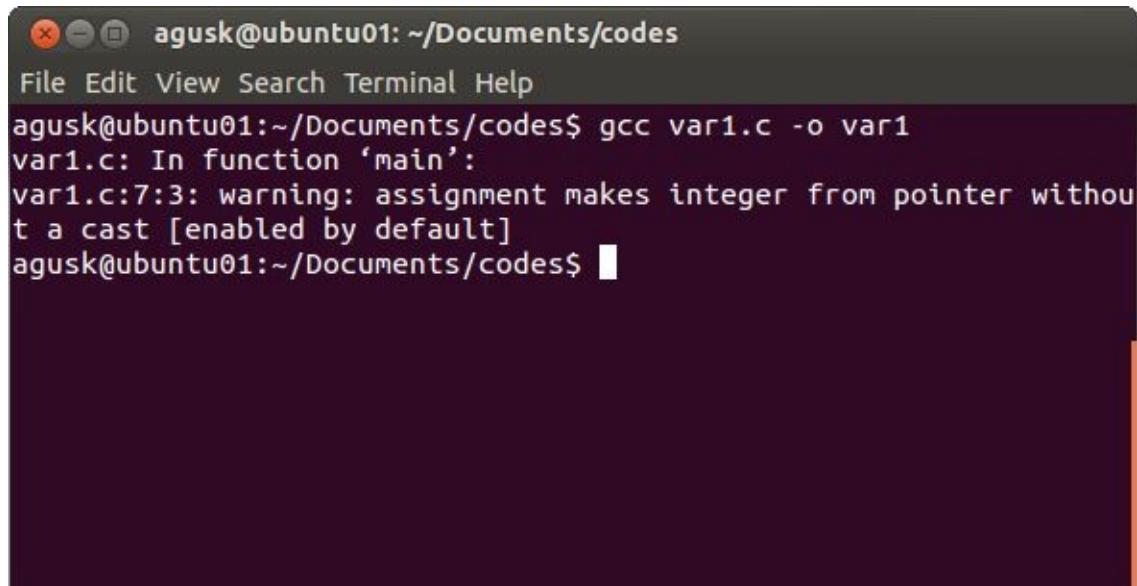

int main() {
    int n;
    int i, j;

    n="hello";

    return 0;
}
```

Save this code as file, called **var1.c**.

Try to compile this file. You will get a warning message as shown Figure as below

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc var1.c -o var1
var1.c: In function 'main':
var1.c:7:3: warning: assignment makes integer from pointer without a cast [enabled by default]
agusk@ubuntu01:~/Documents/codes$
```

## 2.4 Comment

You may explain how to work on your code with writing C. To do it, you can use // and /\* \*/ syntax. Here is sample code:

```
// bank account
char accountCode;

/* parameters*/
int p1, p2, p3, p4;
```

## 2.5 Input & Output on Console

You may want to show message on console using C. You can use **printf()** to write message on console. printf() also can be passed parameters inside using %d for integer numeric and %f for floating numeric. For char data type, we can use %c for passing parameter.

Here is a sample code

```
#include <stdio.h>

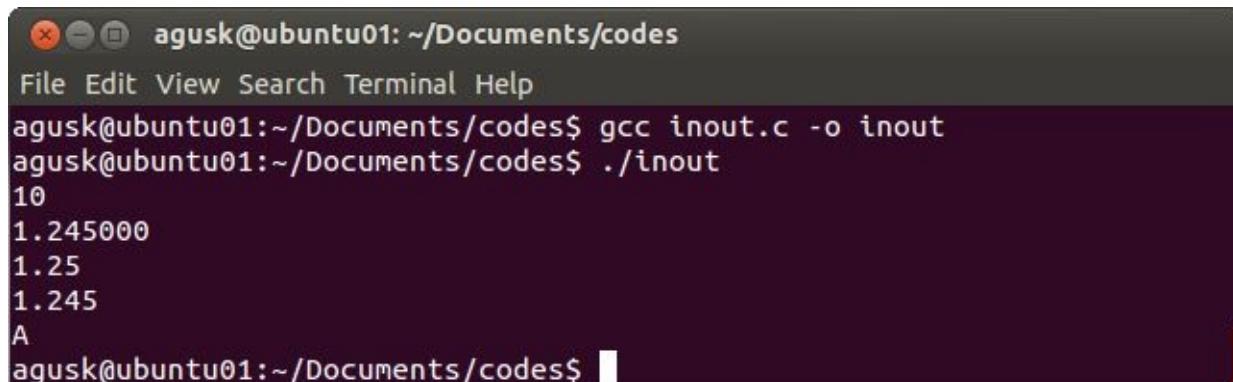

int main() {
    int n = 10;
    float m = 1.245;
    char c = 'A';

    printf("%d \n", n);
    printf("%f \n", m);
    printf("%.2f \n", m);
    printf("%.3f \n", m);
    printf("%c \n", c);

    return 0;
}
```

Save this code into a file, called **inout.c**.

Compile and run this code

The screenshot shows a terminal window with the following content:

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc inout.c -o inout
agusk@ubuntu01:~/Documents/codes$ ./inout
10
1.245000
1.25
1.245
A
agusk@ubuntu01:~/Documents/codes$
```

You can see on %f that wrote floating data with 6 decimal digits. You can specify the number of decimal digit by passing numeric after dot (.), for instance, %.2f and %.3f.

## 2.6 Arithmetic Operations

C supports the four basic arithmetic operations such as addition, subtraction, multiplication, and division. The following is the code illustration for basic arithmetic:

```
#include <stdio.h>

int main() {
    int a, b, c;
    a = 10;
    b = 6;

    c = a + b;
    printf("%d + %d = %d\n", a, b, c);

    c = a - b;
    printf("%d - %d = %d\n", a, b, c);

    c = a * b;
    printf("%d * %d = %d\n", a, b, c);

    float d = a / b;
    printf("%d / %d = %.2f\n", a, b, d);

    float e =(float)a / b;
    printf("%d / %d = %.2f\n", a, b, e);

    return 0;
}
```

Save this program into a file, called **arith.c**. Compile and run it.

Program run:

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc arith.c -o arith
agusk@ubuntu01:~/Documents/codes$ ./arith
10 + 6 = 16
10 - 6 = 4
10 * 6 = 60
10 / 6 = 1.00
10 / 6 = 1.67
agusk@ubuntu01:~/Documents/codes$
```

## 2.7 Mathematical Functions

C provides math library to manipulate mathematical operations. You must include **math.h** to implement mathematical operations.

Here is an illustration code for mathematical functions usage:

```
#include <stdio.h>
#include <stdlib.h>

#include <math.h>

int main() {
    float a;
    float b;
    float pi = 3.14;

    a = 0.25;
    printf("value a = %.2f \n", a);

    b = abs(-a);
    printf("abs(a)=%.2f \n", b);

    b = acos(a);
    printf("acos(a)=%.2f \n", b);

    b = asin(a);
    printf("asin(a)=%.2f \n", b);

    b = atan(a);
    printf("abs(a)=%.2f \n", b);

    b = atan2(a, 5);
    printf("atan(a, 5)=%.2f \n", b);

    b = cos(a);
    printf("cos(a)=%.2f \n", b);

    b = sin(a);
    printf("sin(a)=%.2f \n", b);

    b = tan(a);
    printf("tan(a)=%.2f \n", b);

    b = sqrt(a);
    printf("sqrt(a)=%.2f \n", b);

    return 0;
}
```

Save this code into a file, called **mathdemo.c**. Then compile and run it. Because we use **math.h**, we add **-lm** parameter on compiling.

```
$ gcc mathdemo.c -lm -o mathdemo
$ ./mathdemo
```

A program output can be seen in Figure below.

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc mathdemo.c -lm -o mathdemo
agusk@ubuntu01:~/Documents/codes$ ./mathdemo
value a = 0.25
abs(a)=0.00
acos(a)=1.32
asin(a)=0.25
abs(a)=0.24
atan(a,5)=0.05
cos(a)=0.97
sin(a)=0.25
tan(a)=0.26
sqrt(a)=0.50
agusk@ubuntu01:~/Documents/codes$
```

## 2.8 Comparison Operators

You may determine equality or difference among variables or values. Here is the list of comparison operators:

<code>==</code>	is equal to
<code>!=</code>	is not equal
<code>&gt;</code>	is greater than
<code>&lt;</code>	is less than
<code>&gt;=</code>	is greater than or equal to
<code>&lt;=</code>	is less than or equal to

This is sample code for comparison usage

```
#include <stdio.h>

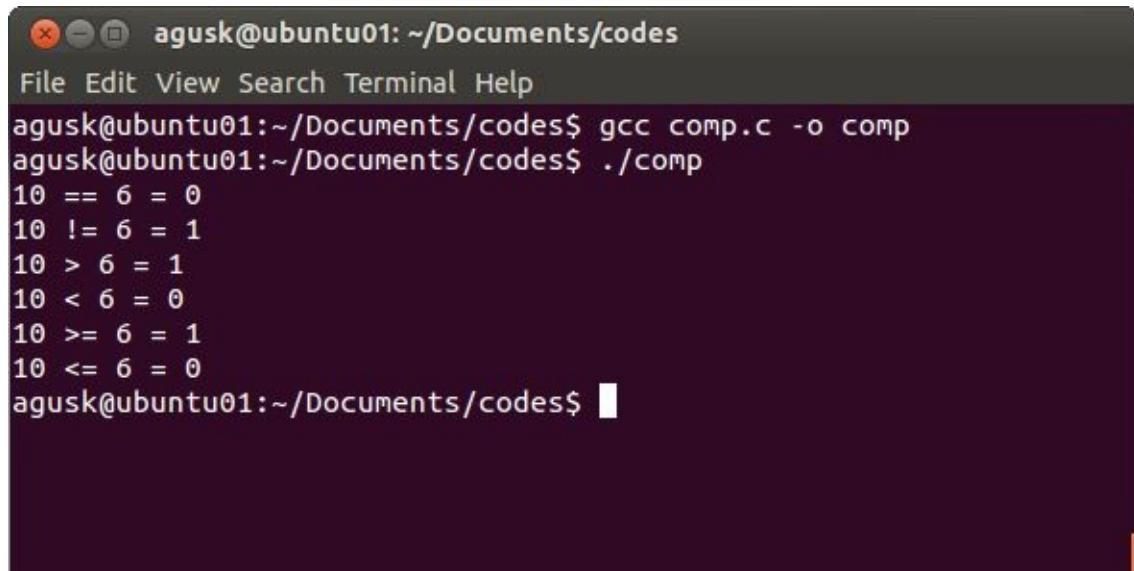

int main() {
    int a, b;
    a = 10;
    b = 6;

    printf("%d == %d = %d\n", a, b, a==b);
    printf("%d != %d = %d\n", a, b, a!=b);
    printf("%d > %d = %d\n", a, b, a>b);
    printf("%d < %d = %d\n", a, b, a<b);
    printf("%d >= %d = %d\n", a, b, a>=b);
    printf("%d <= %d = %d\n", a, b, a<=b);

    return 0;
}
```

Save this code as file, called **comp.c**.

Here is a sample of program output.

```
agusk@ubuntu01:~/Documents/codes$ gcc comp.c -o comp
agusk@ubuntu01:~/Documents/codes$ ./comp
10 == 6 = 0
10 != 6 = 1
10 > 6 = 1
10 < 6 = 0
10 >= 6 = 1
10 <= 6 = 0
agusk@ubuntu01:~/Documents/codes$
```

## 2.9 Logical Operators

These operators can be used to determine the logic between variables or values.

&&	and
	or
!	not

To illustrate how to use logical operators in C code, you can write this code.

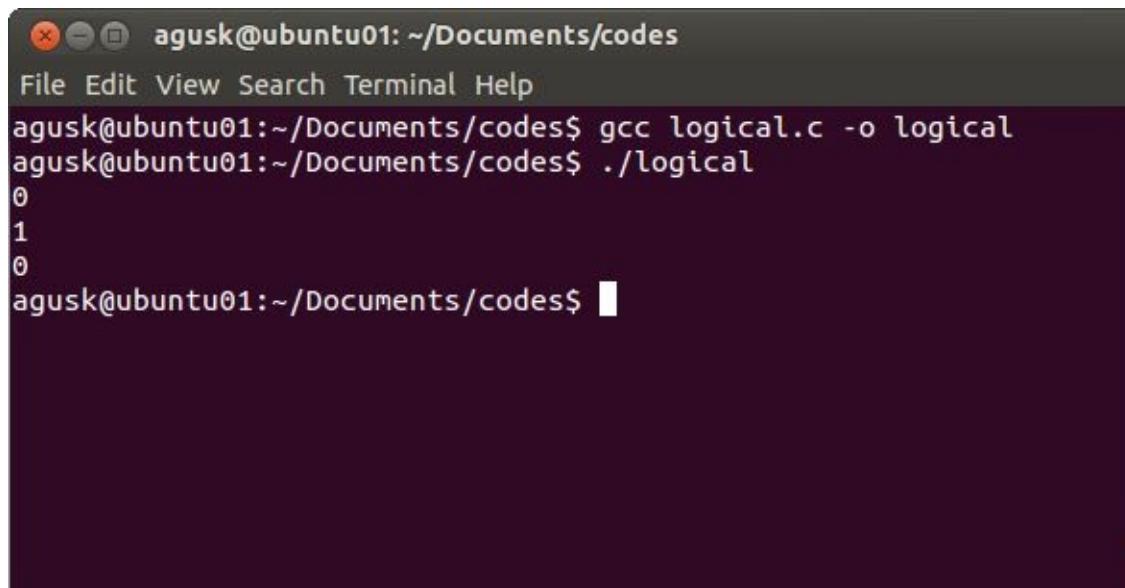

```
#include <stdio.h>

int main() {
    int a, b;
    a = 5;
    b = 8;

    printf("%d \n", a>b && a!=b);
    printf("%d \n", !(a>=b));
    printf("%d \n", a==b || a>b);

    return 0;
}
```

Save this code into a file, **logical.c**. Compile and run it.

The screenshot shows a terminal window with the following content:

```
agusk@ubuntu01: ~/Documents/codes
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc logical.c -o logical
agusk@ubuntu01:~/Documents/codes$ ./logical
0
1
0
agusk@ubuntu01:~/Documents/codes$
```

## 2.10 Increment and Decrement

Imagine you have operation as below

```
num = num + 1;
```

you can simply this syntax use ++.

```
num++;
```

using the same approach for this case

```
num = num - 1;
```

you can use — syntax.

```
num--;
```

Now how to implement them in code. Let's write this code.

```
#include <stdio.h>

int main() {
    int a = 10;

    a++;
    printf("%d \n", a);

    a++;
    printf("%d \n", a);

    ++a;
    printf("%d \n", a);

    a--;
    printf("%d \n", a);

    a--;
    printf("%d \n", a);

    --a;
    printf("%d \n", a);

    return 0;
}
```

Save this code into a file, called **incdec.c**.

Compile and run it. Here is sample of program output.

agusk@ubuntu01: ~/Documents/codes

File Edit View Search Terminal Help

agusk@ubuntu01:~/Documents/codes\$ gcc incdec.c -o incdec

agusk@ubuntu01:~/Documents/codes\$ ./incdec

11

10

agusk@ubuntu01:~/Documents/codes\$ █

## 2.11 Decision

There are two approaches to build decision on C. We can use *if..then* and *switch..case*.

### 2.11.1 if..then

Syntax model for *if..then* can be formulated as below:

```
if (conditional) {  
    // do something  
}else{  
    // do another job  
}
```

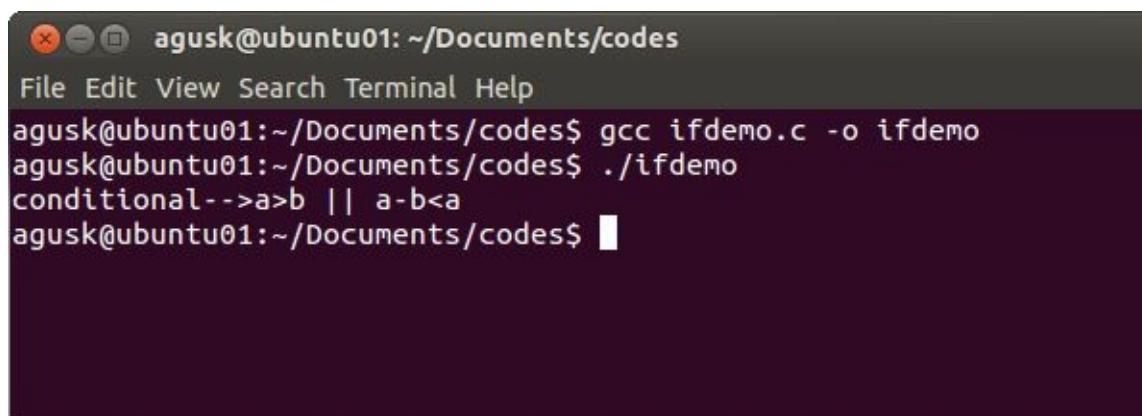

conditional can be obtained by logical or/and comparison operations.

Here is the sample code:

```
#include <stdio.h>  
  
int main() {  
    int a, b;  
    a = 5;  
    b = 8;  
  
    if(a>b || a-b<a){  
        printf("conditional-->a>b || a-b<a \n");  
    }else{  
        printf(..another \n);  
    }  
    return 0;  
}
```

Save this program into a file, called **ifdemo.c**. Then, run this file.

Program run:

The screenshot shows a terminal window with a dark background and light-colored text. The title bar reads "agusk@ubuntu01: ~/Documents/codes". The menu bar includes "File", "Edit", "View", "Search", "Terminal", and "Help". The command line shows the user's directory as "agusk@ubuntu01:~/Documents/codes\$". The user runs the command "gcc ifdemo.c -o ifdemo", followed by "./ifdemo". The output of the program, "conditional-->a>b || a-b<a", is displayed in pink. The terminal prompt "agusk@ubuntu01:~/Documents/codes\$" is shown again at the bottom.

```
agusk@ubuntu01: ~/Documents/codes$ gcc ifdemo.c -o ifdemo  
agusk@ubuntu01: ~/Documents/codes$ ./ifdemo  
conditional-->a>b || a-b<a  
agusk@ubuntu01: ~/Documents/codes$
```

## 2.11.2 switch..case

*switch..case* can be declared as below:

```
switch(option){
    case option1:
        // do option1 job
        break;
    case option2:
        // do option2 job
        break;
}
```

Here is the sample code of *switch..case* usage:

```
#include <stdio.h>

int main() {
    // you can obtain input value from keyboard
    // or any input device
    int input = 3;

    switch(input){
    case 1:
        printf("choose 1\n");
        break;
    case 2:
        printf("choose 2\n");
        break;
    case 3:
    case 4:
        printf("choose 3\n");
        break;
    }
    return 0;
}
```

Save this code into a file, called **switch.c**. Try to build and run it.

Program run:

agusk@ubuntu01: ~/Documents/codes

File Edit View Search Terminal Help

```
agusk@ubuntu01:~/Documents/codes$ ls
a.out      comp.c    ifdemo.c   inout.c    mathdemo.c  var1
arith     comp.c~   ifdemo.c~  logical    mathdemo.c~ var1.c
arith.c   hello     incdec    logical.c  switch.c   var1.c~
arith.c~  hello.c  incdec.c logical.c~ switch.c~  var.c
comp      hello.c~ incdec.c~ mathdemo   var        var.c~

agusk@ubuntu01:~/Documents/codes$ gcc switch.c -o switch
```

```
agusk@ubuntu01:~/Documents/codes$ ./switch
```

```
choose 3
```

```
agusk@ubuntu01:~/Documents/codes$
```

## 2.12 Iterations

Iteration operation is useful when we do repetitive activities. We use `for` and `while` syntax

### 2.12.1 For

The simple scenario that illustrates iteration scenario is to show list of number. We do iteration until the number value less than 10.

```
#include <stdio.h>

int main() {
    int i;
    for(i=0;i<10;i++){
        printf("data %d\n",i);
    }
    return 0;
}
```

Save this code into a file, called `for.c`. Compile and run it.

Here is a program output:

The screenshot shows a terminal window titled "agusk@ubuntu01: ~/Documents/codes". The window contains the following text:

```
File Edit View Search Terminal Help
agusk@ubuntu01:~/Documents/codes$ gcc for.c -o for
agusk@ubuntu01:~/Documents/codes$ ./for
data 0
data 1
data 2
data 3
data 4
data 5
data 6
data 7
data 8
data 9
agusk@ubuntu01:~/Documents/codes$
```

### 2.12.2 While

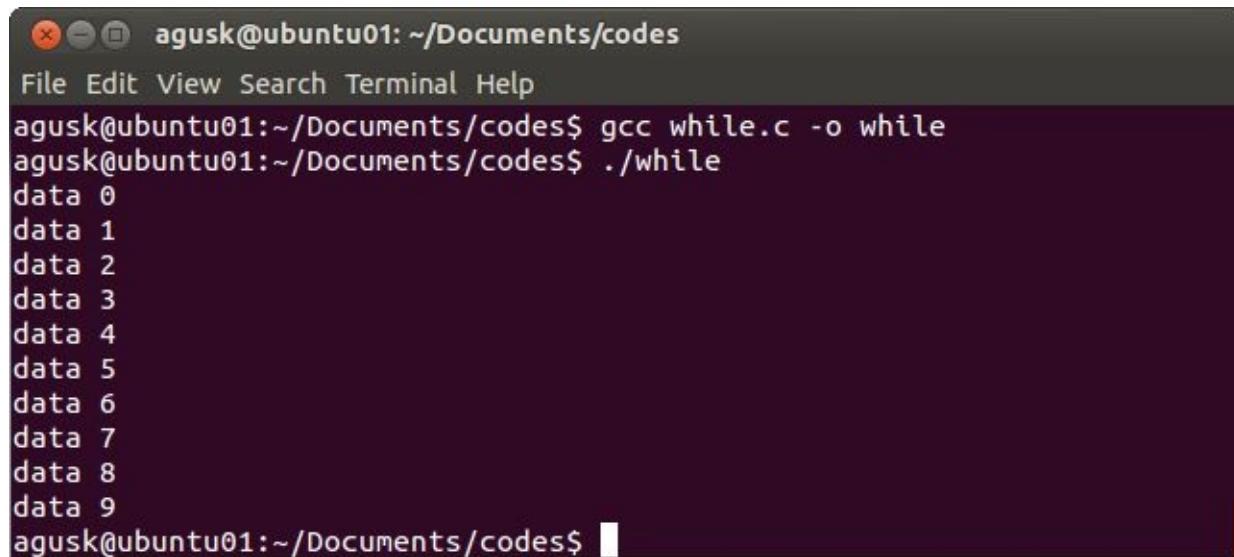

The following is the same code like 2.12.1 scenario but it uses `while` syntax.

```
#include <stdio.h>

int main() {
    int num = 0;
```

```
    while(num<10){  
        printf("data %d\n",num);  
        num++;  
    }  
    return 0;  
}
```

Save this code into a file, called **while.c**. Try to compile and run it.

The screenshot shows a terminal window with the following session:

```

## 2.13 Struct

We can define a struct to declare a new data type. We use struct keyword. For illustration, we define new data type, called employee.

Create a file, called **structdemo.c**, and write this code.

```
#include <stdio.h>

// define a struct
struct employee{
    int id;
    char name[10];
    char country[5];
};

int main() {
    // declare struct variable
    struct employee emp;

    // set values
    emp.id = 10;
    sprintf(emp.name, "jane");
    sprintf(emp.country, "DE");

    // display
    printf("id: %d, name: %s, country: %s\n", emp.id, emp.name, emp.country);

    return 0;
}
```

Save this code.

Now you compile and run this program.

```
$ gcc -o structdemo structdemo.c
$ ./structdemo
```

A sample output of program can be seen in Figure below, Mac platform.

```
src — bash — 80x12
agusk$ ls
address.c      dtwopointer.c    iffdemo.c      multiarray.c   while.c
arith.c         for.c          incdec.c      pointer.c
arraydemo.c    funcdemo.c    inout.c        refpointer.c
comp.c          hello         logical.c    structdemo.c
dpointer.c     hello.c       mathdemo.c   switch.c
agusk$ gcc -o structdemo structdemo.c
agusk$ ./structdemo
id: 10, name: jane, country: DE
agusk$
```

### **3. Array and Pointer**

This chapter explains how to work with array and Pointer.

## 3.1 Array

In this section, we build an array using C. For illustration, we develop single and multi dimensional array.

### 3.1.1 Defining An Array

We can define an array using [] syntax. For instance, we define array of int and char.

```
int numbers[5];
char chars[10];
```

We also can construct array from struct.

```
struct employee{
    int id;
    char name[10];
    char country[5];
};

struct employee list[5];
```

### 3.1.2 Basic Array Operations

After declared an array, we can set and get data on array. For illustration, create a file, called **arraydemo.c**, and write this code.

```
#include <stdio.h>

struct employee{
    int id;
    char name[10];
    char country[5];
};

int main() {
    // define array
    int numbers[5];
    char chars[10];
    struct employee list[5];

    // insert data
    int i;
```

```

for(i=0;i<5;i++){
    numbers[i] = i;

    list[i].id = i;
    sprintf(list[i].name,"usr %d",i);
    sprintf(list[i].country,"DE");
}
sprintf(chars,"hello c");

// display data
for(i=0;i<5;i++){
    printf("%d %c\n",numbers[i],chars[i]);
    printf("struct. id: %d, name: %s, country: %s \n",
           list[i].id,list[i].name,list[i].country);
}
printf("%s\n",chars);

return 0;
}

```

Save this code and try to compile and run.

```

$ gcc -o arraydemo arraydemo.c
$ ./arraydemo

```

A sample output can be seen in Figure below.

```

arraydemo.c      funcdemo.c      inout.c        refpointer.c
comp.c          hello         logical.c      structdemo
dpointer.c      hello.c       mathdemo.c    structdemo.c
agusk$ gcc -o arraydemo arraydemo.c
agusk$ ./arraydemo
0 h
struct. id: 0, name: usr 0, country: DE
1 e
struct. id: 1, name: usr 1, country: DE
2 l
struct. id: 2, name: usr 2, country: DE
3 l
struct. id: 3, name: usr 3, country: DE
4 o
struct. id: 4, name: usr 4, country: DE
hello c
agusk$

```

## 3.2 Multidimensional Array

We can create multidimensional array, for instance two dimensional, we can use [][].

For testing, you can create a file, called **multiarrray.c** and write this code.

```
#include <stdio.h>

int main() {
    // define Multidimensional demenarray
    int matrix[3][5];

    // insert data
    int i,j;
    for(i=0;i<3;i++){
        for(j=0;j<5;j++){
            matrix[i][j] = i+j;
        }
    }

    // display data
    for(i=0;i<3;i++){
        for(j=0;j<5;j++){
            printf("%d ",matrix[i][j]);
        }
        printf("\n");
    }

    return 0;
}
```

Save this. Then, try to compile and run.

```
$ gcc -o multiarrray multiarrray.c
$ ./multiarrray
```

A sample output can be seen in Figure below.

```
src — bash — 80x17
agusk$ ls
address.c      dpointer.c    hello.c      mathdemo.c   structdemo.c
arith.c         dtwopointer.c ifdemo.c    multiarray.c switch.c
arraydemo      for.c        incdec.c   pointer.c    while.c
arraydemo.c    funcdemo.c   inout.c     refpointer.c
comp.c          hello       logical.c
agusk$ gcc -o multiarray multiarray.c
agusk$ ./multiarray
0 1 2 3 4
1 2 3 4 5
2 3 4 5 6
agusk$
```

### 3.3 Pointer

A pointer is a programming language object, whose value refers to (or “points to”) another value stored elsewhere in the computer memory using its address. A pointer references a location in memory, and obtaining the value stored at that location is known as dereferencing the pointer (source:

[http://en.wikipedia.org/wiki/Pointer\\_\(computer\\_programming\)](http://en.wikipedia.org/wiki/Pointer_(computer_programming)) ).

To obtain memory address of a variable, we can use & syntax. For instance, create a file, called **address.c**, and write this code.

```
#include <stdio.h>

int main(int argc, const char* argv[]) {

    int n;
    n = 10;

    printf("value n: %d \n",n);
    printf("address n: %x \n",&n);

    return 0;
}
```

Save this file. Then, try to compile and run.

```
$ gcc -o address address.c
$ ./address
```

If success, we obtain memory address of variable n. A sample output of program can be seen in Figure below.

```
agusk$ ls
address      comp.c      hello       logical.c   structdemo
address.c    dpointer.c  hello.c     mathdemo.c  structdemo.c
arith.c      dtwopointer.c ifdemo.c   multiarray  switch.c
arraydemo   for.c       incdec.c   multiarray.c while.c
arraydemo.c funcdemo.c  inout.c    pointer.c
agusk$ gcc -o address address.c
agusk$ ./address
value n: 10
address n: 5a37ebbc
agusk$
```

### 3.3.1 Basic Pointer

To declare a pointer of a specific data type, we can use \* syntax. This variable consists of memory address of our pointer variable.

For illustration, create a file, called **pointer.c**, and write this code.

```
#include <stdio.h>

int main(int argc, const char* argv[]) {

    int n;
    int* nPtr;

    n = 10;
    nPtr = &n;

    printf("value n: %d \n",n);
    printf("address n: %x \n", (unsigned int)&n);

    printf("value nPtr: %x \n", (unsigned int)nPtr);
    printf("address nPtr: %x \n", (unsigned int)&nPtr);
    printf("value pointer nPtr: %d \n", *nPtr);

    return 0;
}
```

Save this file. Then, compile and run this file.

```
$ gcc -o pointer pointer.c
$ ./pointer
```

You can see a value of nPtr is memory address of variable n. If n is set value 10, then value of pointer nPtr which we declare as \*nPtr is the same value with value of variable n.

A sample of program output is shown in Figure below.

```
agusk$ ls
address      comp.c      hello       logical.c   structdemo
address.c    dpointer.c  hello.c     mathdemo.c  structdemo.c
arith.c      dtwopointer.c ifdemo.c   multiarray  switch.c
arraydemo   for.c       incdec.c   multiarray.c while.c
arraydemo.c funcdemo.c  inout.c    pointer.c
agusk$ gcc -o pointer pointer.c
agusk$ ./pointer
value n: 10
address n: 50b28bbc
value nPtr: 50b28bbc
address nPtr: 50b28bb0
value pointer nPtr: 10
agusk$
```

### 3.3.2 Dynamic Array

In this section, we will create a dynamic array using pointer. In general, we can declare an array using [] with size. Now we can declare our array with dynamic size.

Basically, when we add a new value, we allocate memory and then attach it to array. For illustration, we define array with size 10. Then, we add some values to this array.

Create a file, called **dpointer.c**, and write this code.

```
#include <stdio.h>
#include <stdlib.h>

int main(int argc, const char* argv[]) {

    // define dynamic array of pointer
    int *numbers; // single array pointer

    // a number of array
    int N = 10;
```

```

// allocate memory
numbers = malloc( N * sizeof(int));

// set values
int i;
for(i=0;i<N;i++){
    numbers[i] = i+3;
}

// display values
for(i=0;i<N;i++){
    printf("%d ",numbers[i]);
}
printf("\n");

// free memory
free(numbers);

return 0;
}

```

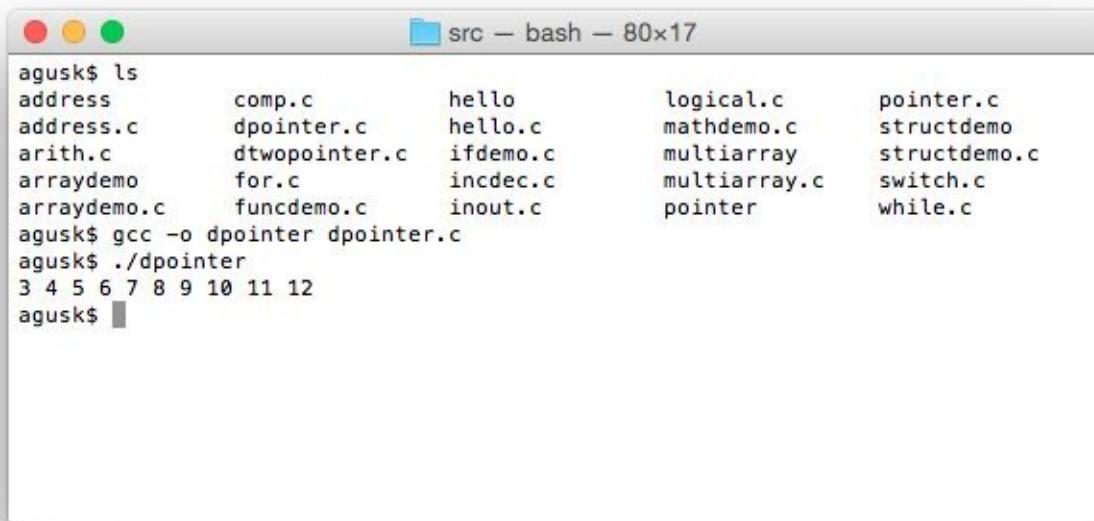

Save this code. Try to compile and run it.

```

$ gcc -o dpointer dpointer.c
$ ./dpointer

```

A program output can be seen in Figure below.

The screenshot shows a terminal window titled "src — bash — 80x17". The window contains the following text:

```

agusk$ ls
address      comp.c      hello       logical.c   pointer.c
address.c    dpointer.c  hello.c     mathdemo.c  structdemo
arith.c      dtwopointer.c ifdemo.c   multiarray  structdemo.c
arraydemo   for.c       incdec.c   multiarray.c switch.c
arraydemo.c funcdemo.c inout.c    pointer     while.c
agusk$ gcc -o dpointer dpointer.c
agusk$ ./dpointer
3 4 5 6 7 8 9 10 11 12
agusk$

```

Another sample, we also define dynamic array with multidimensional. For instance, we create two dimensional dynamic array. Create a file, called **dtwopointer.c**, and write this

code.

```
#include <stdio.h>
#include <stdlib.h>

int main(int argc, const char* argv[]) {

    // define dynamic array of pointer
    int **matrix; // two dimensional array pointer

    // a number of array
    int M = 3;
    int N = 5;

    // allocate memory
    matrix = malloc( M * sizeof(int*));

    // set values
    int i,j;
    for(i=0;i<M;i++){
        matrix[i] = malloc( N * sizeof(int));
        for(j=0;j<N;j++){
            matrix[i][j] = i + j;
        }
    }

    // display values
    for(i=0;i<M;i++){
        for(j=0;j<N;j++){
            printf("%d ",matrix[i][j]);
        }
        printf("\n");
    }

    // free memory
    free(matrix);

    return 0;
}
```

Save this code. Compile and run this file.

```
$ gcc -o dtwopointer dtwopointer.c
$ ./dtwopointer
```

A sample output is shown in Figure below.

```
src — bash — 80x17
agusk$ ls
address      dpointer     hello.c      multiarray    switch.c
address.c    dpointer.c   ifdemo.c    multiarray.c  while.c
arith.c       dtwopointer.c incdec.c   pointer
arraydemo    for.c        inout.c     pointer.c
arraydemo.c  funcdemo.c  logical.c  structdemo
comp.c        hello       mathdemo.c structdemo.c
agusk$ gcc -o dtwopointer dtwopointer.c
agusk$ ./dtwopointer
0 1 2 3 4
1 2 3 4 5
2 3 4 5 6
agusk$
```

## **4. Functions**

This chapter explains how to create function using C.

## 4.1 Creating Function

Declaring function in C can be written as follows

```
void foo(){
    printf("foo() was called\n");
}
```

We put this function on above main() function. Then, we can call this function, for instance foo().

For illustration, we can create a file, called **funcdemo.c** , and write this code.

```
#include <stdio.h>

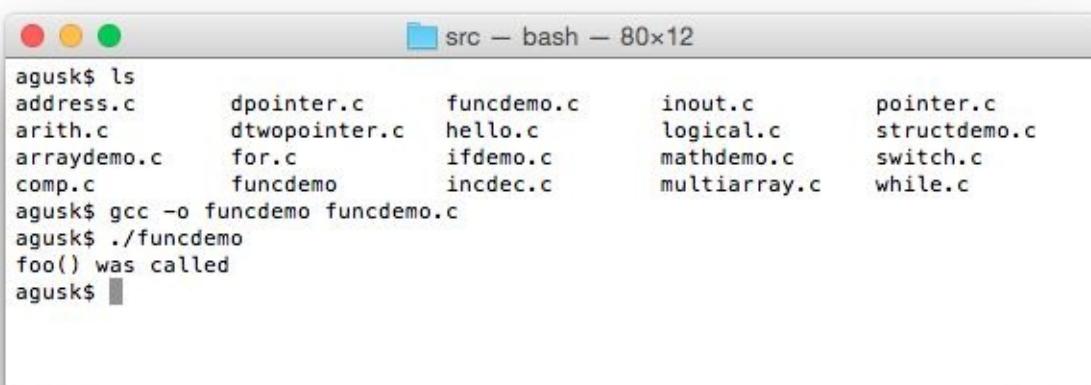

void foo(){
    printf("foo() was called\n");
}

int main(int argc, const char* argv[]) {
    foo();
    return 0;
}
```

Save this file. Compile and run this program.

```
$ gcc -o funcdemo funcdemo.c
$ ./funcdemo
```

A sample of program output can be seen in Figure below.

The screenshot shows a terminal window titled "src - bash - 80x12". The window contains the following text:

```
agusk$ ls
address.c      dpointer.c     funcdemo.c     inout.c      pointer.c
arith.c        dtwopointer.c   hello.c       logical.c    structdemo.c
arraydemo.c    for.c          ifdemo.c     mathdemo.c   switch.c
comp.c         funcdemo      incdec.c    multiarray.c while.c
agusk$ gcc -o funcdemo funcdemo.c
agusk$ ./funcdemo
foo() was called
agusk$
```

We also can declare a function on below of main() function but we must declare our function name.

Add this code on **funcdemo.c** file.

```
#include <stdio.h>

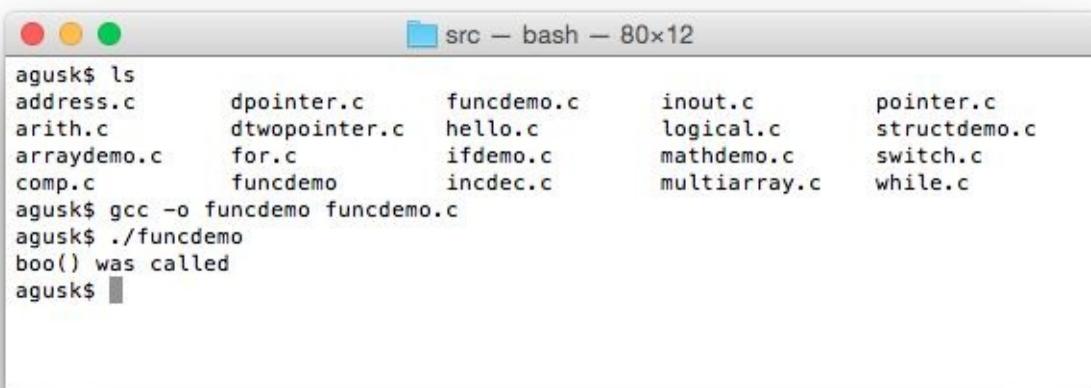

// implicit declaration for functions
void boo();

int main(int argc, const char* argv[]) {

    boo();
    return 0;
}

void boo(){
    printf("boo() was called\n");
}
```

If we compile and run this code, we will get a response, shown in Figure below.

The screenshot shows a terminal window titled "src - bash - 80x12". The user has listed several C source files (address.c, arith.c, arraydemo.c, comp.c, dpointer.c, dtwopointer.c, for.c, funcdemo.c, hello.c, ifdemo.c, incdec.c, inout.c, logical.c, mathdemo.c, multiarray.c, pointer.c, structdemo.c, switch.c, while.c) and then compiled them into an executable named "funcdemo" using the command "gcc -o funcdemo funcdemo.c". Finally, the user runs the executable with "./funcdemo", which outputs the message "boo() was called".

```
agusk$ ls
address.c      dpointer.c      funcdemo.c      inout.c      pointer.c
arith.c        dtwopointer.c   hello.c        logical.c   structdemo.c
arraydemo.c    for.c          ifdemo.c       mathdemo.c  switch.c
comp.c         funcdemo       incdec.c     multiarray.c while.c
agusk$ gcc -o funcdemo funcdemo.c
agusk$ ./funcdemo
boo() was called
agusk$
```

## 4.2 Function with Parameters and Returning Value

You may want to create a function that has parameters and a return value. It is easy because you just call *return* into your function.

Add this code in funcdemo.c file. Write this code.

```
#include <stdio.h>

// implicit declaration for functions
int add(int a, int b);

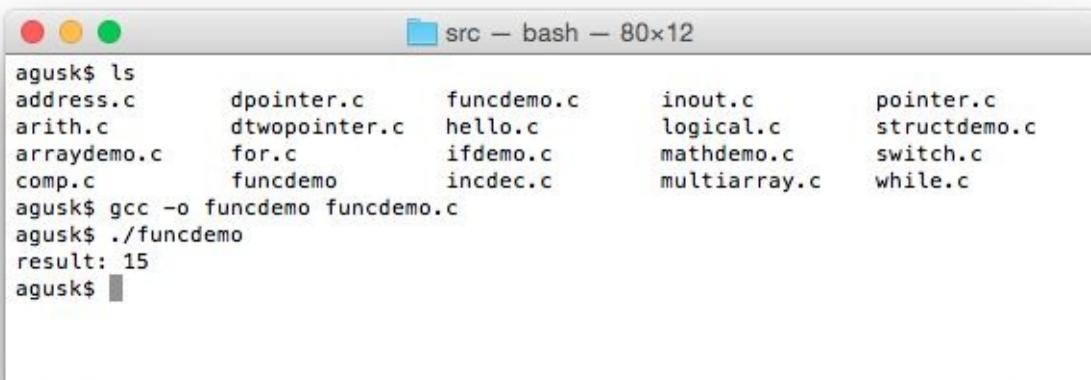

int main(int argc, const char* argv[]) {

    int result = add(10,5);
    printf("result: %d\n",result);

    return 0;
}

int add(int a, int b){
    return a + b;
}
```

Try to compile and run this file.

The screenshot shows a terminal window titled "src - bash - 80x12". The user runs "ls" to list files, then compiles "funcdemo.c" into "funcdemo" using "gcc -o funcdemo funcdemo.c". Finally, the user runs the compiled program "./funcdemo" which outputs "result: 15".

```
agusk$ ls
address.c      dpointer.c      funcdemo.c      inout.c      pointer.c
arith.c         dtwopointer.c   hello.c        logical.c   structdemo.c
arraydemo.c    for.c          ifdemo.c       mathdemo.c  switch.c
comp.c          funcdemo       incdec.c     multiarray.c while.c
agusk$ gcc -o funcdemo funcdemo.c
agusk$ ./funcdemo
result: 15
agusk$
```

## 4.3 Function with Array Parameters

We also can declare a function with array as parameters. To know how array size, our function should declare array size.

Write this code into your program for illustration.

```
#include <stdio.h>

// implicit declaration for functions
double mean(int numbers[], int size);

int main(int argc, const char* argv[]) {

    int numbers[8] = {8, 4, 5, 1, 4, 6, 9, 6};
    double ret_mean = mean(numbers, 8);
    printf("mean: %.2f\n", ret_mean);

    return 0;
}

double mean(int numbers[], int size){
    int i, total;
    double temp;

    for (i = 0; i < size; ++i){
        total += numbers[i];
    }

    temp = (double)total / (double)size;
    return temp;
}
```

Now you can compile and run this program.

The screenshot shows a terminal window titled "src - bash - 80x12". The user has run several commands:

- "ls" to list files in the directory, showing files like address.c, arith.c, arraydemo.c, comp.c, dpointer.c, dtwopointer.c, for.c, funcdemo.c, hello.c, ifdemo.c, incdec.c, inout.c, logical.c, mathdemo.c, multiarray.c, pointer.c, structdemo.c, switch.c, and while.c.
- "gcc -o funcdemo funcdemo.c" to compile the "funcdemo.c" file into an executable named "funcdemo".
- "./funcdemo" to run the compiled program, which outputs "mean: 4101.25".

## 4.4 Function and Pointer

We can pass pointer as parameters in our function. For illustration, we can create swap() to swap our values.

Try to run this program.

```
#include <stdio.h>

// implicit declaration for functions
void swap(int *px, int *py);

int main(int argc, const char* argv[]) {

    int *x, *y;
    int a, b;

    a = 10;
    b = 5;

    // set value
    x = &a;
    y = &b;

    printf("value pointer x: %d \n", *x);
    printf("value pointer y: %d \n", *y);

    swap(x,y);
    printf("swap()\n");
    printf("value pointer x: %d \n", *x);
    printf("value pointer y: %d \n", *y);
    return 0;
}

void swap(int *px, int *py){
    int temp;

    // store pointer px value to temp
    temp = *px;
    // set pointer px by py value
    *px = *py;
    // set pointer py by temp value
    *py = temp;
}
```

A sample of program output can be seen in Figure below.

```
src — bash — 80x12
address.c      dpointer.c     funcdemo.c    inout.c      pointer.c
arith.c        dtwopointer.c  hello.c       logical.c    structdemo.c
arraydemo.c   for.c         ifdemo.c     mathdemo.c  switch.c
comp.c         funcdemo     incdec.c    multiarray.c while.c
agusk$ gcc -o funcdemo funcdemo.c
agusk$ ./funcdemo
value pointer x: 10
value pointer y: 5
swap()
value pointer x: 5
value pointer y: 10
agusk$
```

## **5. I/O Operations**

This chapter explains how to work with I/O operations.

## 5.1 Getting Started

In this section, we learn how to work with I/O operation. The following is our scenario to illustrate how deal with I/O using C:

- Reading input from keyboard
- Reading program arguments
- Writing data into a file
- Reading data from a file

## 5.2 Reading Input from Keyboard

We can read input from keyboard in many ways. The following is a list of function for reading input from keyboard:

- getchar()
- gets()
- scanf()
- 

We will implement theses functions on next section.

### 5.2.1 getchar() and putchar() functions

getchar() function is used to get a character from keyboard and putchar() function is used to print a character to Terminal.

For illustration, create a file, called **keyboard.c**, and write this code.

```
#include <stdio.h>

void getchar_putchar();

int main() {
    getchar_putchar();
    return 0;
}

void getchar_putchar(){
    int c;

    printf ("Type a character: ");
    c = getchar();
    printf ("char: %c\n",c);
    putchar(c);
    printf("\n");
}
```

Compile and run this program.

```
$ gcc -o keyboard keyboard.c
$ ./keyboard
```

You can see the program output in the following Figure below.

```
src - bash - 80x12
agusk$ gcc -o keyboard keyboard.c
agusk$ ./keyboard
Type a character: g
char: g
g
agusk$
```

## 5.2.2 gets() and puts() functions

gets() is used to read a text. It will stop to read if you type newline (ENTER key). Unfortunately, gets() is unsafe function(). We can use fgets() to read text with length limitation.

For testing, we add get\_puts() function on **keyboard.c** file, and write this code.

```
#include <stdio.h>

void gets_puts();

int main() {
    gets_puts();
    return 0;
}

void gets_puts(){
    printf("----unsafe input----\n");
    char name[256];

    printf ("Your name: ");
    gets (name);
    printf ("name: %s\n", name);
    puts(name);

    printf("----fget() input----\n");
    name[0] = '\0'; // clear
    printf ("Your name: ");
    fgets(name, 256, stdin);
```

```
    printf ("name: %s\n", name);
    puts(name);
}
```

Save this code. Try to compile and run this program.

A sample output can be seen in Figure below.

```
src - bash - 80x18
agusk$ gcc -o keyboard keyboard.c
agusk$ ./keyboard
-----unsafe input-----
warning: this program uses gets(), which is unsafe.
Your name: zahra
name: zahra
zahra
-----fget() input-----
Your name: jane
name: jane

jane

agusk$
```

### 5.2.3 scanf() function

Another approach, we can use scanf() function to read a text.

For illustration, we add scanf() function on **keyboard.c** file, and write this code.

```
#include <stdio.h>

void scanf_demo();

int main() {
    scanf_demo();
    return 0;
}

void scanf_demo(){
    int num;
    char c;
    char city[15];
```

```
float dec;

printf("Please enter an integer value: ");
scanf("%d", &num );

// %c ignores space characters
printf("Please enter a character: ");
scanf(" %c", &c );

printf("Please enter a city name (no space): ");
scanf("%s", city );

printf("Please enter a decimal value: ");
scanf("%f", &dec );

printf("\n-----result-----\n");
printf("number = %d\n", num );
printf("character = %c\n", c );
printf("city name = %s\n", city );
printf("decimal number = %f\n", dec );
}
```

Save this code. Compile and run this program

```
agusk$ gcc -o keyboard keyboard.c
agusk$ ./keyboard
Please enter an integer value: 12
Please enter a character: h
Please enter a city name (no space): berlin
Please enter a decimal value: 87.45

-----result-----
number = 12
character = h
city name = berlin
decimal number = 87.449997
agusk$
```

## 5.3 Reading Program Arguments

We can read arguments and its length from our program. This information already pass to main() function.

For illustration, create a file, called **argument.c**, and write this code.

```
#include <stdio.h>

int main(int argc, const char* argv[]) {

    int i;

    printf("total argument: %d\n", argc-1);
    if(argc>1){
        for(i=1;i<argc;i++){
            printf("%s\n", argv[i]);
        }
    }

    return 0;
}
```

Compile and run this program.

```
$ gcc -o argument argument.c
$ ./argument
```

A sample output can be seen in Figure below.

The screenshot shows a terminal window titled "src — bash — 80x12". The window contains the following text:

```
agusk$ gcc -o argument argument.c
agusk$ ./argument -n 2 -m 25 -H -R
total argument: 6
-n
2
-m
25
-H
-R
agusk$
```

## 5.4 Writing Data Into A File

We can write data into a file. The following is the algorithm for writing data:

- Create a file using `fopen()` function
- Write data into a file using `fprintf()` and `fputs()` functions
- Close a file using `fclose()` function

For testing, we create data into a file, **demo.txt**. For implementation, create a file, called **filewrite.c**, and write this code.

```
#include <stdio.h>

int main(int argc, const char* argv[]) {

    int i;
    FILE *f;

    f = fopen("demo.txt", "w+");

    for(i=0;i<5;i++){
        fprintf(f, "fprintf message %d\n", i);
        fputs("fputs message\n", f); // no format
    }

    fclose(f);
    printf("Data was written into a file\n");

    return 0;
}
```

Save this code. Compile and run this program.

```
$ gcc -o filewrite filewrite.c
$ ./filewrite
```

A sample output can be seen in Figure below.

A screenshot of a terminal window titled "src — bash — 80x12". The window shows the following command-line session:

```
agusk$ ls
address.c      dpointer.c    funcdemo.c    keyboard.c    switch.c
argument       dtwopointer.c  hello.c       logical.c    while.c
argument.c     fileread.c    ifdemo.c     mathdemo.c   multiarray.c
arith.c        filewrite.c   incdec.c    pointer.c    structdemo.c
arraydemo.c   for.c        inout.c      keyboard
comp.c         funcdemo
agusk$ gcc -o filewrite filewrite.c
agusk$ ./filewrite
Data was written into a file
agusk$
```

If success, it will generate **demo.txt**. You can open this file using text editor.

A screenshot of a terminal window titled "src — nano — 80x12". The window shows the content of the file "demo.txt" in the nano text editor:

```
GNU nano 2.0.6          File: demo.txt
printf message 0
fputs message
printf message 1
fputs message
printf message 2
fputs message
printf message 3
[ Read 10 lines ]

^X Exit      ^J Justify   ^W Where Is   ^V Next Page  ^U UnCut Text ^T To Spell
```

## 5.5 Reading Data From A File

We also can read data from a file using fgetc() function. For testing, create file, called **fileread.c**, and write this code.

```
#include <stdio.h>

int main(int argc, const char* argv[]) {

    char ch;
    FILE *f;

    printf("Reading a file....\n");
    f = fopen("demo.txt", "r");
    if(f==NULL){
        printf("Failed to read file\n");
        return 0;
    }

    while((ch = fgetc(f)) != EOF )
        printf("%c",ch);

    fclose(f);

    return 0;
}
```

Compile and this program.

```
$ gcc -o fileread fileread.c
$ ./fileread
```

A sample output can be seen in Figure below.

src — bash — 80x16

```
arraydemo.c      fwrite      ifdemo.c      mathdemo.c
comp.c          fwrite.c    incdec.c    multiarray.c
agusk$ gcc -o fileread fileread.c
agusk$ ./fileread
Reading a file....
fprintf message 0
fputs message
fprintf message 1
fputs message
fprintf message 2
fputs message
fprintf message 3
fputs message
fprintf message 4
fputs message
agusk$ █
```

## **6. String Operations**

This chapter explains how to work with String operations in C.

## 6.1 Concatenating Strings

If you have a list of string, you can concatenate into one string. You can use `strcat()` function from `string.h` header. For illustration, create a file, called **stringdemo.c**, and write the following code.

```
#include <stdio.h>
#include <string.h>

void concatenating();

int main(int argc, const char* argv[]) {
    concatenating();
    return 0;
}

void concatenating(){
    printf("====concatenating===\n");

    char str1[30] = "hello";
    char str2[10] = "wolrd";

    strcat(str1,str2);
    printf("result: %s\n",str1);
}
```

Compile and run this program.

```
$ gcc -o stringdemo stringdemo.c
$ ./stringdemo
```

A program output can be seen in Figure below.

```
src — bash — 80x11
address.c      demo.txt      filewrite.c    incdec.c      multiarray.c
argument       dpointer.c   for.c          inout.c      pointer.c
argument.c     dtwopointer.c funcdemo.c   funcdemo.c  stringdemo.c
arith.c        fileread.c   hello.c       keyboard.c  structdemo.c
arraydemo.c   fileread.c   ifdemo.c     keyboard.c  switch.c
comp.c         filewrite.c ifdemo.c     logical.c  while.c
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
====concatenating===
result: helloworld
agusk$
```

## 6.2 String To Numeric

Sometime you want to do math operations but input data has String type. To convert String type into numeric, you can use `sscanf()` function for String to numeric. Add `string_to_numeric()` function on **stringdemo.c** and write this code.

```
#include <stdio.h>
#include <string.h>

void string_to_numeric();

int main(int argc, const char* argv[]) {
    string_to_numeric();
    return 0;
}

void string_to_numeric(){
    printf("====string_to_numeric====\n");
    char str1[10] = "10";
    char str2[10] = "28.74";

    int num1;
    float num2;

    sscanf(str1, "%d", &num1);
    sscanf(str2, "%f", &num2);

    printf("num1: %d\n", num1);
    printf("num2: %f\n", num2);
}
```

Compile and run this program. If success, you get the following of program output.

```
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
====string_to_numeric===
num1: 10
num2: 28.740000
agusk$
```

## 6.3 Numeric to String

It is easy to convert numeric to String type, you can use sprintf() function. You can get String type automatically. For illustration, add numeric\_to\_string() function and write this code.

```
#include <stdio.h>
#include <string.h>

void numeric_to_string();

int main(int argc, const char* argv[]) {
    numeric_to_string();
    return 0;
}

void numeric_to_string(){
    printf("====numeric_to_string===\n");
    int n = 10;
    float m = 23.78;

    char num1[10];
    char num2[10];

    sprintf(num1, "%d", n);
    sprintf(num2, "%.2f", m);

    printf("num1: %s\n", num1);
    printf("num2: %s\n", num2);
}
```

Compile and run this program.

```
src — bash — 80x11
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
=====numeric_to_string=====
num1: 10
num2: 23.78
agusk$
```

## 6.4 String Parser

The simple solution to parsing String uses *strtok()* function with delimiter parameter. For example, you have String data with ; delimiter and want to parse it. Here is sample code by adding *string\_parser()* function.

```
#include <stdio.h>
#include <string.h>

void string_parser();

int main(int argc, const char* argv[]) {
    string_parser();
    return 0;
}

void string_parser(){
    char cities[40] = "Tokyo;Berlin;London;New York";
    char token[2] = ";";
    char* city;

    printf("cities: %s\n", cities);

    city = strtok(cities, token);
    while(city != NULL){
        printf("%s\n", city );
        city = strtok(NULL, token);
    }
}
```

Compile and run this program.

The screenshot shows a terminal window titled 'src - bash - 80x12'. The user has typed 'gcc -o stringdemo stringdemo.c' to compile the program. After compilation, they run the executable with './stringdemo'. The output displays the string 'cities: Tokyo;Berlin;London;New York' followed by each city name on a new line: Tokyo, Berlin, London, and New York. The terminal prompt 'agusk\$' is visible at the end.

```
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
cities: Tokyo;Berlin;London;New York
Tokyo
Berlin
London
New York
agusk$
```

## 6.5 Check String Data Length

You can use `strlen()` function from `string.h` header to get the length of string data. For testing, add `string_length()` function and write this code.

```
#include <stdio.h>
#include <string.h>

void string_length();

int main(int argc, const char* argv[]) {
    string_length();
    return 0;
}

void string_length(){
    char str[20] = "Hello world";
    printf("str: %s\n", str);
    printf("length: %d\n", (int)strlen(str));
}
```

Compile and run this program.

The screenshot shows a terminal window titled "src - bash - 80x12". The window contains the following text:

```
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
str: Hello world
length: 11
agusk$
```

## 6.6 Copy Data

You may copy some characters from String data. To do it, you can use *strcpy()* and *strncpy()* functions. For illustration, add *string\_copy()* function and write the following code.

```
#include <stdio.h>
#include <string.h>

void string_copy();

int main(int argc, const char* argv[]) {
    string_copy();
    return 0;
}

void string_copy(){
    char str[15] = "Hello world";
    char new_str[20];

    strcpy(new_str,str);
    printf("str: %s\n",str);
    printf("new_str: %s\n",new_str);

    memset(new_str, '\0', sizeof(new_str));
    strncpy(new_str,str,5);
    printf("strncpy-new_str: %s\n",new_str);
}
```

Compile and run this program.

The screenshot shows a terminal window titled "src - bash - 80x12". The terminal displays the following command-line session:

```
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
str: Hello world
new_str: Hello world
strncpy-new_str: Hello
```

## 6.7 Exploring Characters

You may get a character by position index. `string_var[index]` syntax provides this feature. Note 0 is the first index.

For testing, add `string_explore()` function and write this code.

```
#include <stdio.h>
#include <string.h>

void string_explore();

int main(int argc, const char* argv[]) {
    string_explore();
    return 0;
}

void string_explore(){
    char str[15] = "Hello world";
    int index;

    for(index=0;index<strlen(str);index++){
        printf("%c\n",str[index]);
    }
}
```

Compile and run this program.

The screenshot shows a Mac OS X terminal window titled "src — bash — 80x18". The terminal displays the following command-line session:

```
agusk$ gcc -o stringdemo stringdemo.c
agusk$ ./stringdemo
H
e
l
l
o

w
o
r
l
d
agusk$
```

## **7. Building C Library**

This chapter explains how to build a library in C.

## 7.1 Getting Started

Sometimes we create some functions which are used for any application. We can create a library and use it in our C program. In this chapter, we try to build a library using C. There are two library type of library in C, static library and shared library.

## 7.2 Writing C Library

For illustration, we create a library by creating a file, called **mysimplelib.c**, and write this code.

```
#include <stdio.h>

int add(int a,int b){
    return a+b;
}
int subtract(int a,int b){
    return a-b;
}
int multiply(int a,int b){
    return a*b;
}
```

Save this program.

After that, we create a header file for our library. Create a file, called **mysimple.h**, and write this code.

```
/*
header of libmysimple for static and shared libraries
*/
extern int add(int a,int b);
extern int subtract(int a,int b);
extern int multiply(int a,int b);
```

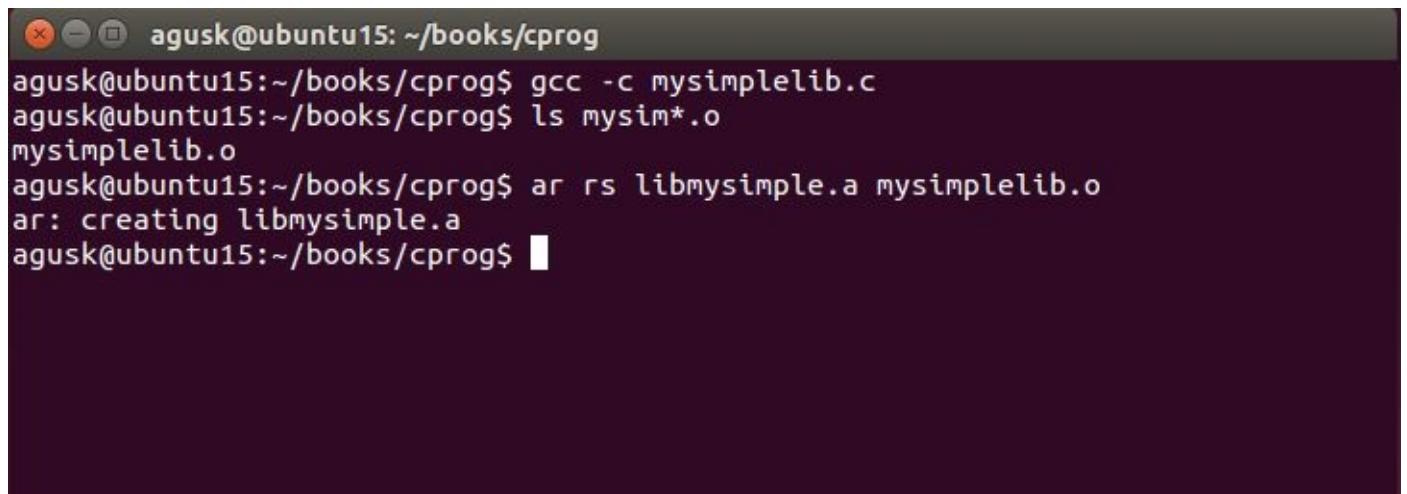

## 7.3 Compiling and Testing

In this section, we try to compile our library, **mysimplelib.c**, to be static library and shared library.

### 7.3.1 Static Library

Firstly, we compile our library, **mysimplelib.c**, to be a static library, called **libmysimple.a**.

```
$ gcc -c mysimplelib.c  
$ ar rs libmysimple.a mysimplelib.o
```

The screenshot shows a terminal window with a dark background and light-colored text. The window title is "agusk@ubuntu15: ~/books/cprog". The terminal output is as follows:

```
agusk@ubuntu15:~/books/cprog$ gcc -c mysimplelib.c  
agusk@ubuntu15:~/books/cprog$ ls mysim*.o  
mysimplelib.o  
agusk@ubuntu15:~/books/cprog$ ar rs libmysimple.a mysimplelib.o  
ar: creating libmysimple.a  
agusk@ubuntu15:~/books/cprog$
```

To access our static library, we create a simple app. Create a file, called **mysimpletest.c**, and write this code.

```
#include <stdio.h>  
#include "mysimple.h"  
  
int main(int argc, const char* argv[]) {  
  
    int a,b,c;  
  
    a = 5;  
    b = 3;  
  
    c = add(a,b);  
    printf("%d + %d = %d\n",a,b,c);  
  
    c = subtract(a,b);  
    printf("%d - %d = %d\n",a,b,c);
```

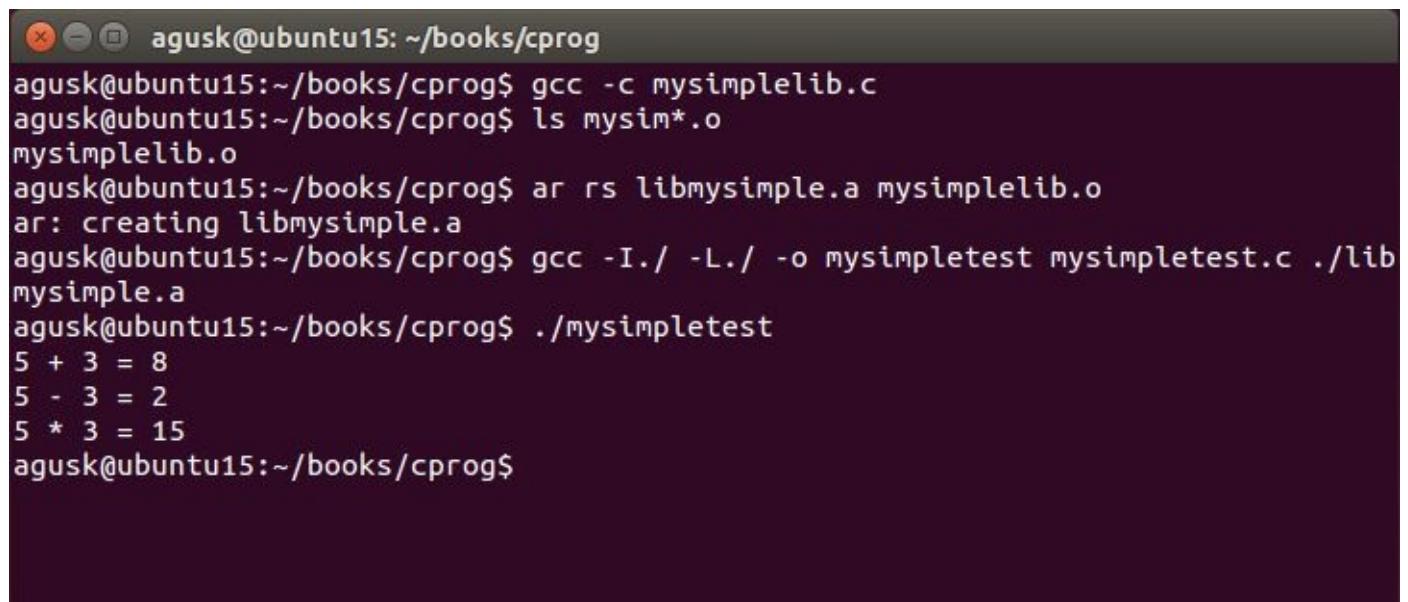

```
c = multiply(a, b);
printf("%d * %d = %d\n", a, b, c);

return 0;
}
```

Consider our static library, **libmysimple.a** , and header file for library, **mysimple.h** are located into the same folder. Now you can compile and run this program.

```
$ gcc -I./ -L./ -o mysimpletest mysimpletest.c ./libmysimple.a
$ ./mysimpletest
```

A program output can be seen in Figure below.

The screenshot shows a terminal window with a dark background and light-colored text. It displays the following command-line session:

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -c mysimplelib.c
agusk@ubuntu15:~/books/cprog$ ls mysim*.o
mysimplelib.o
agusk@ubuntu15:~/books/cprog$ ar rs libmysimple.a mysimplelib.o
ar: creating libmysimple.a
agusk@ubuntu15:~/books/cprog$ gcc -I./ -L./ -o mysimpletest mysimpletest.c ./lib
mysimple.a
agusk@ubuntu15:~/books/cprog$ ./mysimpletest
5 + 3 = 8
5 - 3 = 2
5 * 3 = 15
agusk@ubuntu15:~/books/cprog$
```

## 7.3.2 Shared Library

We compile our library, **mysimplelib.c**, to be a shared library, called **libmysimple.so** . You can type the following commands.

```
$ gcc -c -fPIC mysimplelib.c
$ gcc -shared -o libmysimple.so mysimplelib.o
```

```
agusk@ubuntu15: ~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -c -fpic mysimplelib.c
agusk@ubuntu15:~/books/cprog$ ls mysimple*.o
mysimplelib.o
agusk@ubuntu15:~/books/cprog$ gcc -shared -o libmysimple.so mysimplelib.o
agusk@ubuntu15:~/books/cprog$ ls libmy*.so
libmysimple.so
agusk@ubuntu15:~/books/cprog$
```

To test our shared library, we can use the same program from **mysimpletest.c** .

Consider share library, **libmysimple.so**, and header file for shared library, **mysimple.h**, are located on the same folder.

You can compile and run our program.

```
$ gcc -I./ -L./ -o mysimpletest mysimpletest.c -lmysimple
$ ./mysimpletest
```

Program output:

```
agusk@ubuntu15: ~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -I./ -L./ -o mysimpletest mysimpletest.c -lmysimple
agusk@ubuntu15:~/books/cprog$ ./mysimpletest
5 + 3 = 8
5 - 3 = 2
5 * 3 = 15
agusk@ubuntu15:~/books/cprog$
```

You can modify shared library file location. For instance, we put our shared library file into /home/agusk/lib. We must add our library folder into LD\_LIBRARY\_PATH. Type this command.

```
export LD_LIBRARY_PATH=/home/agusk/lib:$LD_LIBRARY_PATH
```

Then, you can compile and run our program, mysimpletest .

## **8. Threading**

This chapter explains how to work with threading using C.

## 8.1 Creating Thread

A thread of execution is the smallest unit of processing that a scheduler works on. A process can have multiple threads of execution which are executed asynchronously.

On Linux/Unix, we can create a thread using `pthread_create()` that can be defined as follows.

```
#include <pthread.h>

int pthread_create (pthread_t *thread,
                    const pthread_attr_t *attr,
                    void *(*start_routine) (void *),
                    void *arg);
```

Note:

- `pthread_attr_t` is thread attributes
- `start_routine` is a function that will be executed
- `arg` is argument that passes to function

For illustration, we create a thread by creating a file, called **createthread.c**. Write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>

void* perform(void *arg)
{
    int i;
    int *n = (int *)arg;

    printf("processing from thread\r\n");
    for(i=0;i<(*n);i++)
    {
        printf("%d ",i);
    }
    printf("\r\n");

}

int main(int argc, char* argv[])
{
    pthread_t thread;
    int ret;
    errno = 0;
    int n = 10;
```

```
ret = pthread_create (&thread, NULL, perform, &n);
if (ret)
{
    printf("\n pthread_create() failed with error [%s]\n", strerror(err));
    return -1;
}
int c = getchar(); // hold app to exit
return 0;
}
```

You can see we pass parameter n=10 to function perform(). On function perform(), we just do looping.

Now save this code. To compile and link, you can type the following command.

```
$ gcc -pthread -o createthread createthread.c
```

If success, you can run this app.

```
$ ./createthread
```

The following is sample output.

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ ls
broadcast.c      createthread.c  mutex.c      terminateother.c
condvariable.c   jointhread.c   selfexit.c   threadid.c
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o createthread createthread.c
agusk@ubuntu15:~/books/cprog$ ./createthread
processing from thread
0 1 2 3 4 5 6 7 8 9

agusk@ubuntu15:~/books/cprog$
```

## 8.2 Thread ID

We can obtain the running thread using pthread\_self() and following is its syntax.

```
#include <pthread.h>
pthread_t pthread_self (void);
```

To use this function, you can call pthread\_self() inside thread function.

For illustration, create file, called **threadid.c**, and write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>

void* perform(void *arg)
{
    int i;
    int *n = (int *)arg;
    pthread_t tid;

    printf("processing from thread\r\n");
    /* get the calling thread's ID */
    tid = pthread_self();
    printf("Thread id: %d \r\n", (int)tid);
    for(i=0;i<(*n);i++)
    {
        printf("%d ", i);
    }
    printf("\r\n");

}

int main(int argc, char* argv[])
{
    pthread_t thread;
    int ret;
    errno = 0;
    int n = 10;

    ret = pthread_create (&thread, NULL, perform, &n);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror(errno));
        return -1;
    }
    int c = getchar(); // hold app to exit
    return 0;
}
```

Save this code. Then try to compile and run it.

The following is sample output.

```
agusk@ubuntu15:~/books/cprog$ ls
broadcast.c      createthread.c    selfexit.c      threadid.c
condvariable.c   jointhread.c    terminateother.c  threadid.c~
createthread    mutex.c        threadid
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o threadid threadid.c
agusk@ubuntu15:~/books/cprog$ ./threadid
processing from thread
Thread id: 159737600
0 1 2 3 4 5 6 7 8 9

agusk@ubuntu15:~/books/cprog$
```

## 8.3 Terminating Thread

We can terminate a thread using two approaches, terminating itself and terminating others. We are going to explore these approaches on next section.

### 8.3.1 Terminating Itself

A thread can stop its processing using pthread\_exit(). The following is a syntax of pthread\_exit().

```
#include <pthread.h>

void pthread_exit (void *retval);
```

For illustration, we build app based threading and call function perform(). On function perform(), we do looping and will exit from internal thread after looped index 3 by calling pthread\_exit().

To implement, we create a file, called **selfexit.c**, and write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>

void* perform(void *arg)
{
    int i;
    int *n = (int *)arg;

    printf("processing from thread\r\n");
    for(i=0;i<(*n);i++)
    {
        if(i==3)
        {
            printf("Terminating thread\r\n");
            /* exit this thread */
            pthread_exit((void *)0);
        }
        printf("%d ",i);
    }
    printf("\r\n");
}

int main(int argc, char* argv[])
{
```

```

pthread_t thread;
int ret;
errno = 0;
int n = 10;

ret = pthread_create (&thread, NULL, perform, &n);
if (ret)
{
    printf("\n pthread_create() failed with error [%s]\n", strerror(errno));
    return -1;
}
int c = getchar(); // hold app to exit
return 0;
}

```

Save this code. Compile and run this code.

The following is a sample output.

```

agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ ls
broadcast.c      createthread.c  selfexit.c      threadid.c

processing from thread
0 1 2 Terminating thread

agusk@ubuntu15:~/books/cprog$

```

### 8.3.2 Terminating Others

We also can terminate a thread by calling `pthread_cancel()` with passing thread object.

```

#include <pthread.h>

int pthread_cancel (pthread_t thread);

```

A thread can be configured to enable/disable for canceling thread using `pthread_setcancelstate()`. `pthread_testcancel()` function creates a cancellation point in the calling thread. `pthread_setcancelstate()` and `pthread_testcancel()` functions can be defined as follows

```
#include <pthread.h>
```

```
int pthread_setcancelstate(int state, int *oldstate);
void pthread_testcancel(void);
```

For illustration, we build app to create a thread and try to terminate it using `pthread_cancel()`.

Create a file, called **terminateother.c**, and write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>
#include <unistd.h>

void* perform(void *arg)
{
    int n = 0;

    // I'm not ready to be canceled
    pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    printf("processing from thread\r\n");
    while(1)
    {
        printf("%d ", n);
        n++;

        pthread_testcancel();
        if(n>5)
        {
            // I'm ready to be canceled
            pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, NULL);
        }

        sleep(1);
    }
    printf("\r\n");
}

int main(int argc, char* argv[])
{
    pthread_t thread;
    int ret, status;
    errno = 0;

    ret = pthread_create (&thread, NULL, perform, NULL);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror(err
        return -1;
    }
    sleep(10);
```

```

errno = 0;
status = pthread_cancel(thread);
if (status)
{
    printf("\n pthread_cancel() failed with error [%s]\n", strerror(e
    return -1;
}

int c = getchar(); // hold app to exit
return 0;
}

```

Explanation:

- On main entry main(), we create a thread with passing perform() function
- We hold current process using sleep() for 10 seconds
- After that, we try to terminate a thread by calling pthread\_cancel()
- pthread\_cancel() function returns status value. You can verify this return value
- On perform() function, firstly we call pthread\_setcancelstate() to disable the thread cancelling
- After looping n>5, we enable the thread cancelling
- pthread\_testcancel() function is called to create a cancellation point

Save this code. Compile and run it.

The following is a sample output.

```

agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o terminateother terminateother.c
agusk@ubuntu15:~/books/cprog$ ./terminateother
processing from thread
0 1 2 3 4 5 6 7 8 9
agusk@ubuntu15:~/books/cprog$ 

```

## 8.4 Joining Thread

Joining thread is one of thread synchronization to terminate the executing thread. We can use pthread\_join() and defined as follows.

```
#include <pthread.h>

int pthread_join (pthread_t thread, void **retval);
```

We need to pass thread attribute to enable joining thread. We can use pthread\_attr\_init(), pthread\_attr\_setdetachstate(), and pthread\_attr\_destroy() that can be defined as follows.

```
#include <pthread.h>

int pthread_attr_init(pthread_attr_t *attr);
int pthread_attr_destroy(pthread_attr_t *attr);
int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);
```

For illustration, we build a simple thread app to compute a simple math equation.

Create a file, called **jointhread.c**, and write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>
#include <unistd.h>
#include <math.h>

void* compute(void *arg)
{
    int i;
    pthread_t tid;
    double result = 0;

    tid = pthread_self();
    printf("processing from thread %ld \r\n", tid);

    // do something
    for(i=0;i<50;i++)
    {
        result = result + sin(i/2);
    }
    printf("Thread %d. Completed, result=%e \r\n", tid, result);

    pthread_exit((void *)0);
}

int main(int argc, char* argv[])
{
```

```

{
    pthread_t thread[5];
    pthread_attr_t attr;
    void *status;
    int i, ret;
    errno = 0;

    // thread attribute
    pthread_attr_init(&attr);
    pthread_attr_setdetachstate(&attr, PTHREAD_CREATE_JOINABLE);

    for(i=0;i<5;i++)
    {
        ret = pthread_create (&thread[i], &attr, compute, NULL);
        if (ret)
        {
            printf("\n pthread_create() failed with error [%s]\n",strerror
                  return -1;
        }
    }
    sleep(2);

    // joining thread
    printf("joining thread\r\n");
    for(i=0;i<5;i++)
    {
        ret = pthread_join(thread[i], &status);
        if (ret)
        {
            printf("\n pthread_join() failed with error [%s]\n",strerror(e
                  return -1;
        }
        printf("Completed join with thread %ld. Status: %ld\n", i,(int)s
    }

    int c = getchar(); // hold app to exit

    return 0;
}

```

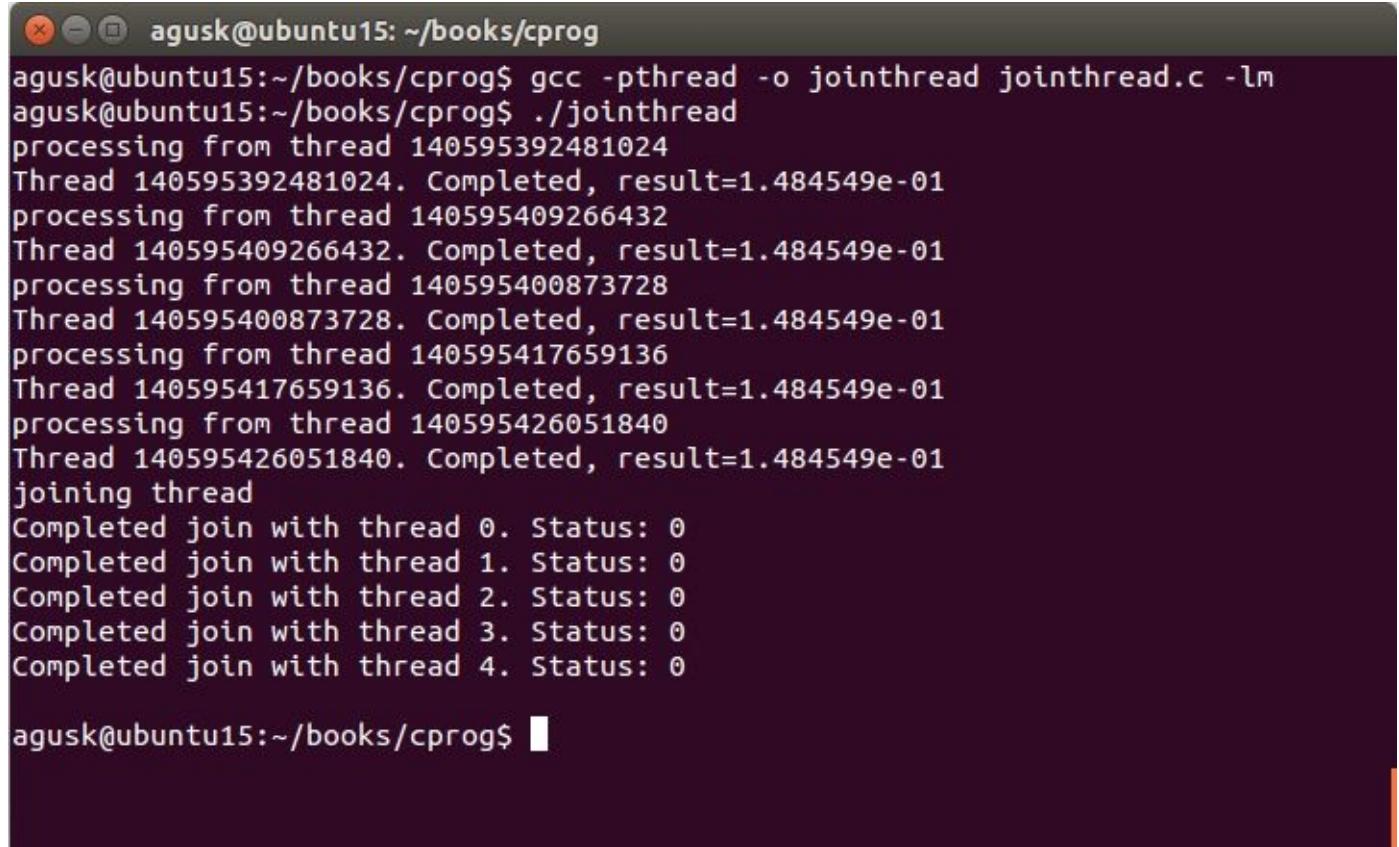

## Explanation:

- On main() entry point, we initialize thread attribute using pthread\_attr\_init() and pthread\_attr\_setdetachstate() to activate joining thread
- We create 5 threads using pthread\_create()
- After 2 seconds, we call pthread\_join() to wait 5 exiting threads
- On computer() function, we calculate simple math
- If finished, it call pthread\_exit()

Save this code. Because we use math.h, we add library -lm on compiling and linking. The following is a syntax to compile this code.

```
$ gcc -pthread -o joithread joithread.c -lm  
$ ./joithread
```

Now you can run it. The sample output is shown Figure below.

```
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o joithread joithread.c -lm  
agusk@ubuntu15:~/books/cprog$ ./joithread

agusk@ubuntu15:~/books/cprog$
```

## 8.5 Thread Mutex

You have resources such as data variable, file, database which can be accessed only by a thread. It's called mutex. For illustration, you have data which is stored on variable n. You also have 5 threads to access this data. The first rule is data variable can be accessed by one thread. It means data variable will be locked so another thread cannot access it.

Mutex is one of thread synchronization mechanism to control accessing resource.

You can implement thread mutex using the following functions.

```
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *restrict mutex,
                      const pthread_mutexattr_t *restrict attr);
int pthread_mutex_destroy(pthread_mutex_t *mutex);
int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

Note:

- pthread\_mutex\_init() initialize mutex object
- pthread\_mutex\_destroy() destroy mutex object
- pthread\_mutex\_lock() lock mutex object
- pthread\_mutex\_unlock() unlock/release mutex object

For implementation, we create a file, called **mutex.c**. Firstly we define headers and global variables. Write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>
#include <unistd.h>

pthread_t thread[5];
int total_finished_jobs;
pthread_mutex_t lock;
```

Variable total\_finished\_jobs can be accessed by only one thread.

On main() point entry, we instantiate mutex object and create 5 threads.

```
int main(int argc, char* argv[])
{
    int i, ret;
    errno = 0;
```

```

total_finished_jobs = 0;

if (pthread_mutex_init(&lock, NULL) != 0)
{
    printf("\n pthread_mutex_init() failed with error [%s]\n", strerror
          return 1;
}

for(i=0;i<5;i++)
{
    ret = pthread_create (&thread[i], NULL, perform_job, NULL);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror
              return -1;
    }
}

int c = getchar(); // hold app to exit
pthread_mutex_destroy(&lock);

return 0;
}

```

Each thread calls `perform_job()` function. When access variable `total_finished_jobs`, we try to lock object `lock`. After that, we update a value of `total_finished_jobs`.

The following is implementation of `perform_job()` function.

```

void* perform_job(void *arg)
{
    int i;
    pthread_t tid;

    tid = pthread_self();
    printf("processing from thread %ld \r\n",tid);
    printf("Thread %d. Started Job. \r\n",tid);

    // do something for doing job
    for(i=0;i<20;i++)
    {
        sleep(1);
    }

    // update job counter
    pthread_mutex_lock(&lock);
    total_finished_jobs++;
    printf("Thread %d. Finished Job. \r\n",tid);
    printf("Total current finished job: %d \r\n",total_finished_jobs);
    pthread_mutex_unlock(&lock);
}

```

Now save all code. You can compile and run it.

You can see a sample output on the following Figure.

```
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o mutex mutex.c
agusk@ubuntu15:~/books/cprog$ ./mutex
processing from thread 140110273353472

Total current finished job: 3
Thread 140110306924288. Finished Job.
Total current finished job: 4
Thread 140110298531584. Finished Job.
Total current finished job: 5

agusk@ubuntu15:~/books/cprog$
```

## 8.6 Condition Variables

We have learned thread synchronization using thread mutex. Now we explore another thread synchronization using condition variables in controlling accessing resource.

There are two methods to implement condition variables on thread synchronization:

- Signaling
- Broadcasting

Each method will be explained on next section.

### 8.6.1 Signaling

The idea of signaling is after you access a resource you must notify to another thread to start accessing resource. To implement it, we can use the following functions.

```
#include <pthread.h>

int pthread_cond_init(pthread_cond_t *restrict cond,
                      const pthread_condattr_t *restrict attr);

int pthread_cond_wait(pthread_cond_t *restrict cond,
                      pthread_mutex_t *restrict mutex);

int pthread_cond_destroy(pthread_cond_t *cond);
```

To notify another thread, you can use `pthread_cond_signal()` which is defined as below.

```
#include <pthread.h>

int pthread_cond_signal(pthread_cond_t *cond);
```

For illustration, we create two threads that act as producer and consumer. Producer can write data and consumer can only read data. The data can be accessed by one thread, either producer or consumer.

Let's start to create a file, called **condvariable.c**. Firstly we define headers and global variables.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>
#include <unistd.h>
```

```

#define BUFF_LEN 30

int buffer[BUFF_LEN];
int index_put=0, index_get=0;
int count = 0;
pthread_cond_t empty, get;
pthread_mutex_t lock;

```

On main() entry point, we initialize object mutex and condition variables (empty and fill). We also create 2 thread, producer and consumer.

```

int main(int argc, char* argv[])
{
    pthread_t thread_consumer, thread_producer;
    int ret;
    errno = 0;
    int loops = 15;

    // initialization
    if (pthread_mutex_init(&lock, NULL) != 0)
    {
        printf("\n pthread_mutex_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }
    if (pthread_cond_init(&empty, NULL) != 0)
    {
        printf("\n pthread_cond_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }
    if (pthread_cond_init(&get, NULL) != 0)
    {
        printf("\n pthread_cond_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }

    // create thread
    ret = pthread_create (&thread_consumer, NULL, consumer, &loops);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror(errno));
        return -1;
    }
    ret = pthread_create (&thread_producer, NULL, producer, &loops);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror(errno));
        return -1;
    }

    int c = getchar(); // hold app to exit
    pthread_mutex_destroy(&lock);
    pthread_cond_destroy(&empty);
}

```

```

    pthread_cond_destroy(&get);

    return 0;
}

```

On producer() function we do looping until obtain signal empty. After obtained a signal, we add a value on array buffer. If done, it will notify signal get.

```

void *producer(void *arg)
{
    int i;
    int *loops = (int *)arg;

    for (i = 0; i < (*loops); i++)
    {
        pthread_mutex_lock(&lock);
        while (count == BUFF_LEN)
            pthread_cond_wait(&empty, &lock);

        buffer[index_put] = i;
        index_put = (index_put + 1) % BUFF_LEN;
        count++;

        pthread_cond_signal(&get);
        pthread_mutex_unlock(&lock);
    }
    printf("exit from producer\r\n");
}

```

On consumer() function, firstly we wait signal fill. After obtained signal, we read data from array buffer. If done, we notify signal empty.

```

void *consumer(void *arg)
{
    int i;
    int *loops = (int *)arg;

    for (i = 0; i < (*loops); i++)
    {
        pthread_mutex_lock(&lock);
        while (count == BUFF_LEN)
            pthread_cond_wait(&get, &lock);

        int tmp = buffer[index_get];
        index_get = (index_get + 1) % BUFF_LEN;
        count--;
        printf("Value: %d\r\n", tmp);

        pthread_cond_signal(&empty);
        pthread_mutex_unlock(&lock);
    }
}

```

```
    }
    printf("exit from consumer\r\n");
}
```

Save this code. Compile and run it.

The following is a sample output.

```
agusk@ubuntu15: ~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -pthread -o condvariable condvariable.c
agusk@ubuntu15:~/books/cprog$ ./condvariable
exit from producer
Value: 0
Value: 1
Value: 2
Value: 3
Value: 4
Value: 5
Value: 6
Value: 7
Value: 8
Value: 9
Value: 10
Value: 11
Value: 12
Value: 13
Value: 14
exit from consumer

agusk@ubuntu15:~/books/cprog$
```

## 8.6.2 Broadcasting

We can notify some threads using broadcasting signal. It can use `pthread_cond_broadcast()` and defined as follows.

```
#include <pthread.h>

int pthread_cond_broadcast(pthread_cond_t *cond);
```

What's difference between `pthread_cond_broadcast()` and `pthread_cond_signal()`? `pthread_cond_broadcast()` notifies several threads but `pthread_cond_signal()` notifies a thread.

For illustration, we use same code on previous section (section 8.6.1). In this scenario, we have 2 consumer threads and 1 producer thread.

To start, we create a file, called **broadcast.c**. Firstly, we define headers and global variables. Write this code.

```
#include <stdio.h>
#include <pthread.h>
#include <string.h>
#include <errno.h>
#include <unistd.h>

#define BUFF_LEN 30

int buffer[BUFF_LEN];
int index_put=0, index_get=0;
int count = 0;
pthread_cond_t empty, get;
pthread_mutex_t lock;
```

On main() entry point, we initialize mutex and condition variables. Then we create a producer thread and 2 consumer threads.

```
int main(int argc, char* argv[])
{
    pthread_t thread_consumer[2], thread_producer;
    int ret;
    errno = 0;
    int loops = 15;

    // initialization
    if (pthread_mutex_init(&lock, NULL) != 0)
    {
        printf("\n pthread_mutex_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }
    if (pthread_cond_init(&empty, NULL) != 0)
    {
        printf("\n pthread_cond_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }
    if (pthread_cond_init(&get, NULL) != 0)
    {
        printf("\n pthread_cond_init() failed with error [%s]\n", strerror(errno));
        return 1;
    }

    // create thread
    ret = pthread_create (&thread_consumer[0], NULL, consumer, &loops);
    if (ret)
    {
        printf("\n pthread_create() failed with error [%s]\n", strerror(errno));
        return -1;
    }
    ret = pthread_create (&thread_consumer[1], NULL, consumer, &loops);
```

```

if (ret)
{
    printf("\n pthread_create() failed with error [%s]\n", strerror(error));
    return -1;
}
ret = pthread_create (&thread_producer, NULL, producer, &loops);
if (ret)
{
    printf("\n pthread_create() failed with error [%s]\n", strerror(error));
    return -1;
}

int c = getchar(); // hold app to exit
pthread_mutex_destroy(&lock);
pthread_cond_destroy(&empty);
pthread_cond_destroy(&get);

return 0;
}

```

On producer() function, we insert data after obtained signal empty. Then we call pthread\_cond\_broadcast() to notify all consumer threads.

```

void *producer(void *arg)
{
    int i;
    int *loops = (int *)arg;

    for (i = 0; i < (*loops); i++)
    {
        pthread_mutex_lock(&lock);
        while (count == BUFF_LEN)
            pthread_cond_wait(&empty, &lock);

        buffer[index_put] = i;
        index_put = (index_put + 1) % BUFF_LEN;
        count++;

        pthread_cond_broadcast(&get); //broadcast to consumer
        pthread_mutex_unlock(&lock);
    }
    printf("exit from producer\r\n");
}

```

On consumer() function, we get data from array after obtained signal get. After that, we notify producer thread using pthread\_cond\_signal().

```

void *consumer(void *arg)
{
    int i;

```

```
int *loops = (int *)arg;
pthread_t tid;

tid = pthread_self();
for (i = 0; i < (*loops); i++)
{
    pthread_mutex_lock(&lock);
    while (count == BUFF_LEN)
        pthread_cond_wait(&get, &lock);

    int tmp = buffer[index_get];
    index_get = (index_get + 1) % BUFF_LEN;
    count--;
    printf("Thread consumer id: %ld. Value: %d\r\n", tid, tmp);

    pthread_cond_signal(&empty);
    pthread_mutex_unlock(&lock);
}
printf("exit from consumer\r\n");
}
```

Save all code. Now you can compile and run it.

The following is a sample output.

## **9. Database Programming**

This chapter explains how to create database application using C.

## **9.1 Database Library for C**

C can communicate with database server through database driver. We must install database driver for C before we start to develop database application.

In this chapter, I only focus on MySQL scenarios. Basically, I have already published these codes to Github, <https://github.com/agusk/crud-mysql-c> , last year . You can download and improve these codes.

## 9.2 MySQL

To install MySQL server and client in Ubuntu and its database driver for C, you can try to write this command in terminal

```
$ sudo apt-get install mysql-server mysql-client  
$ sudo apt-get install libmysqlclient-dev
```

After finished, we can do testing.

Firstly, we can start to create simple C application to check MySQL version. Write this code

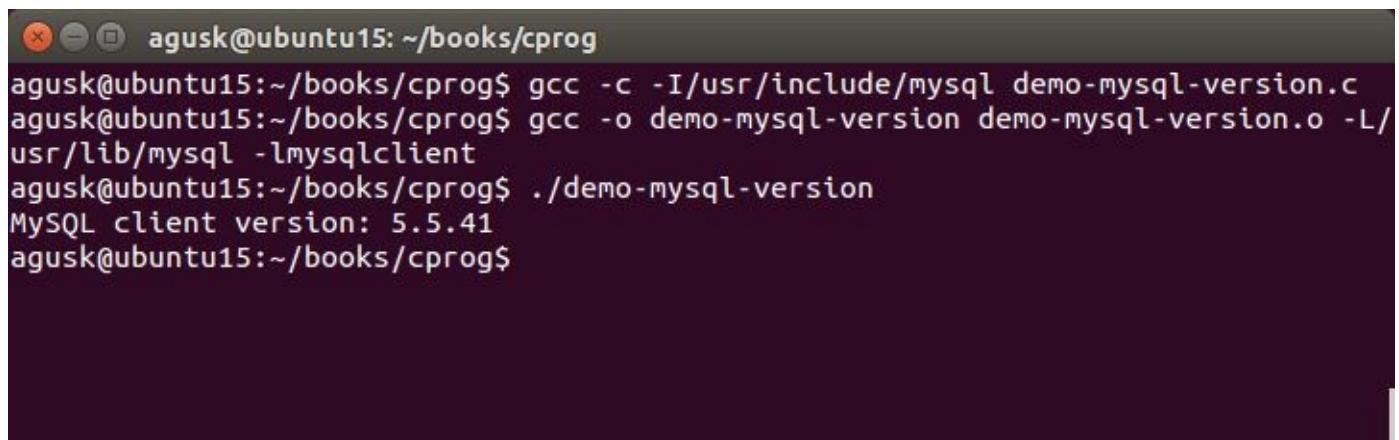

```
#include <my_global.h>  
#include <mysql.h>  
  
int main(int argc, char **argv)  
{  
    printf("MySQL client version: %s\n", mysql_get_client_info());  
    exit(0);  
}
```

Save this program into a file, called **demo-mysql-version.c**.

Now you can compile and run this file.

```
$ gcc -c -I/usr/include/mysql demo-mysql-version.c  
$ gcc -o demo-mysql-version demo-mysql-version.o -L/usr/lib/mysql -lmysql  
$ ./demo-mysql-version
```

If success, you will get MySQL client version.

The screenshot shows a terminal window with the following session:

```
agusk@ubuntu15:~/books/cprog  
agusk@ubuntu15:~/books/cprog$ gcc -c -I/usr/include/mysql demo-mysql-version.c  
agusk@ubuntu15:~/books/cprog$ gcc -o demo-mysql-version demo-mysql-version.o -L/usr/lib/mysql -lmysqlclient  
agusk@ubuntu15:~/books/cprog$ ./demo-mysql-version  
MySQL client version: 5.5.41  
agusk@ubuntu15:~/books/cprog$
```

## 9.3 Connection Test

In this section, we try to test a connection to MySQL server. Create a file, called **demo-connection.c** and write this code.

```
#include <my_global.h>
#include <mysql.h>

int main(int argc, char **argv)
{
    MYSQL *con = mysql_init(NULL);

    if (con == NULL)
    {
        fprintf(stderr, "%s\n", mysql_error(con));
        exit(1);
    }
    printf("connecting to mysql server...\r\n");
    // change host, username, and password
    if (mysql_real_connect(con, "localhost", "root", "password",
                           NULL, 0, NULL, 0) == NULL)
    {
        printf("error: %s\r\n", mysql_error(con));
        mysql_close(con);
        exit(1);
    }
    printf("connected.\r\n");
    printf("closing connection...\r\n");

    mysql_close(con);
    printf("closed.\r\n");

    exit(0);
}
```

Save this program.

Now you can compile and run this file.

```
$ gcc -c -I/usr/include/mysql demo-connection.c
$ gcc -o demo-connection demo-connection.o -L/usr/lib/mysql -lmysqlclient
$ ./demo-connection
```

Program output:

## 9.4 CRUD (Create, Read, Update and Delete) Operations

In this section, we try to develop simple CRUD operations using MySQL and C.

For testing, we create a database, mydatabase, and a table, called product. Run this SQL script into your MySQL server.

```
CREATE SCHEMA `mydatabase` ;  
  
CREATE TABLE `mydatabase`.`product` (  
  `idproduct` INT NOT NULL AUTO_INCREMENT ,  
  `name` VARCHAR(45) NOT NULL ,  
  `price` FLOAT NOT NULL ,  
  `created` DATETIME NOT NULL ,  
  PRIMARY KEY (`idproduct` ));
```

### 9.4.1 Creating Data

We create data into MySQL. In this case, we create a ten data. Create a file, called **demo-create-data.c** and write this code.

```
#include <my_global.h>  
#include <mysql.h>  
#include <time.h>  
#include <string.h>  
  
#define CREATE_DATA "insert into product(name,price,created) values(?, ?, ?)"  
  
int main(int argc, char **argv)  
{  
  
    MYSQL *con = mysql_init(NULL);  
  
    if (con == NULL)  
    {  
        fprintf(stderr, "%s\n", mysql_error(con));  
        exit(1);  
    }  
    printf("connecting to mysql server...\r\n");  
    // change host, username, and password  
    if (mysql_real_connect(con, "localhost", "root", "password",  
                          "mydatabase", 0, NULL, 0) == NULL)  
    {  
        printf("error: %s\r\n", mysql_error(con));  
        mysql_close(con);  
        exit(1);  
    }  
    printf("connected.\r\n");  
    printf("inserting 10 data...\r\n");
```

```
MYSQL_STMT *stmt;

stmt = mysql_stmt_init(con);
if (!stmt)
{
    printf(" mysql_stmt_init(), out of memory\r\n");
    exit(0);
}

if (mysql_stmt_prepare(stmt, CREATE_DATA, strlen(CREATE_DATA)))
{
    printf("mysql_stmt_prepare(), INSERT failed\r\n");
    printf("error: %s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

int i;
time_t now = time(NULL);
char name[10];
unsigned long str_length;
float price;
MYSQL_BIND bind[3];
MYSQL_TIME ts;

memset(bind, 0, sizeof(bind));

bind[0].buffer_type= MYSQL_TYPE_VAR_STRING;
bind[0].buffer= (char *)&name;
bind[0].is_null= 0;
bind[0].length= &str_length;

bind[1].buffer_type= MYSQL_TYPE_FLOAT;
bind[1].buffer= (char *)&price;
bind[1].is_null= 0;
bind[1].length= 0;

bind[2].buffer_type= MYSQL_TYPE_DATETIME;
bind[2].buffer= (char *)&ts;
bind[2].is_null= 0;
bind[2].length= 0;

// bind parameters
if (mysql_stmt_bind_param(stmt, bind))
{
    printf("mysql_stmt_bind_param() failed\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

for(i=1;i<=10;i++)
{
    // set values
```

```

        sprintf(name, "product-%d", i);
        str_length = strlen(name);
        price = 0.23*i;

        // time_t to MYSQL_TIME
        struct tm *now_struct = gmtime(&now);
        ts.year = now_struct->tm_year + 1900;
        ts.month = now_struct->tm_mon + 1;
        ts.day = now_struct->tm_mday;
        ts.hour = now_struct->tm_hour;
        ts.minute = now_struct->tm_min;
        ts.second = now_struct->tm_sec;

        printf("executing data %d...\r\n", i);
        if (mysql_stmt_execute(stmt))
        {
            printf("mysql_stmt_execute(), 1 failed\r\n");
            printf("%s\r\n", mysql_stmt_error(stmt));
            exit(0);
        }

    }
printf("done.\r\n");
printf("closing connection...\r\n");

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    printf("failed while closing the statement\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}
mysql_close(con);
printf("closed.\r\n");

exit(0);
}

```

Save this code.

Now you can compile and run this file.

```

$ gcc -c -I/usr/include/mysql demo-create-data.c
$ gcc -o demo-create-data demo-create-data.o -L/usr/lib/mysql -lmysqlcli
$ ./demo-create-data

```

Program output:

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -c -I/usr/include/mysql demo-create-data.c
agusk@ubuntu15:~/books/cprog$ gcc -o demo-create-data demo-create-data.o -L/usr/

## 9.4.2 Reading Data

In this section, we try to read data from MySQL. For illustration, create a file, called **demo-read-data.c** and write this code.

```
#include <my_global.h>
#include <mysql.h>

int main(int argc, char **argv)
{
    MYSQL *con = mysql_init(NULL);

    if (con == NULL)
    {
        fprintf(stderr, "%s\n", mysql_error(con));
        exit(1);
    }
    printf("connecting to mysql server...\r\n");
    // change host, username, and password
    if (mysql_real_connect(con, "localhost", "root", "password",
                           "mydatabase", 0, NULL, 0) == NULL)
    {
        printf("error: %s\r\n", mysql_error(con));
        mysql_close(con);
        exit(1);
    }
    printf("connected.\r\n");
```

```

printf("show data product\r\n");
if (mysql_query(con, "SELECT * FROM product"))
{
    printf("error: %s\r\n", mysql_error(con));
    mysql_close(con);
    exit(1);
}

MYSQL_RES *result = mysql_store_result(con);
if (result == NULL)
{
    printf("error: %s\r\n", mysql_error(con));
    mysql_close(con);
    exit(1);
}

int num_fields = mysql_num_fields(result);
MYSQL_ROW row;
int i;
while ((row = mysql_fetch_row(result)))
{
    for(i = 0; i < num_fields; i++)
    {
        printf("%s\t", row[i] ? row[i] : "NULL");
    }
    printf("\r\n");
}

mysql_free_result(result);

printf("closing connection...\r\n");

mysql_close(con);
printf("closed.\r\n");

exit(0);
}

```

Save this code.

Now you can compile and run this file.

```

$ gcc -c -I/usr/include/mysql demo-read-data.c
$ gcc -o demo-read-data demo-read-data.o -L/usr/lib/mysql -lmysqlclient
$ ./demo-read-data

```

Program output:

```

agusk@ubuntu15:~/books/cprog$ gcc -c -I/usr/include/mysql demo-read-data.c
agusk@ubuntu15:~/books/cprog$ gcc -o demo-read-data demo-read-data.o -L/usr/lib/

### 9.4.3 Updating Data

In this section, we try to update data, for instance, we update data with id=5. Create a file, called **demo-update-data.c** and write this code.

```

#include <my_global.h>
#include <mysql.h>
#include <string.h>

#define UPDATE_DATA "update product set name = ?, price=? where idproduc

int main(int argc, char **argv)
{
    MYSQL *con = mysql_init(NULL);

    if (con == NULL)
    {
        fprintf(stderr, "%s\n", mysql_error(con));
        exit(1);
    }
```

```
printf("connecting to mysql server...\r\n");
// change host, username, and password
if (mysql_real_connect(con, "localhost", "root", "password",
                       "mydatabase", 0, NULL, 0) == NULL)
{
    printf("error: %s\r\n", mysql_error(con));
    mysql_close(con);
    exit(1);
}
printf("connected.\r\n");

MYSQL_STMT *stmt;

stmt = mysql_stmt_init(con);
if (!stmt)
{
    printf(" mysql_stmt_init(), out of memory\r\n");
    exit(0);
}

if (mysql_stmt_prepare(stmt, UPDATE_DATA, strlen(UPDATE_DATA)))
{
    printf("mysql_stmt_prepare(), UPDATE failed\r\n");
    printf("error: %s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

int i;
char name[10];
unsigned long str_length;
float price;
MYSQL_BIND bind[3];
int product_id;

memset(bind, 0, sizeof(bind));

bind[0].buffer_type= MySQL_TYPE_VAR_STRING;
bind[0].buffer= (char *)&name;
bind[0].is_null= 0;
bind[0].length= &str_length;

bind[1].buffer_type= MySQL_TYPE_FLOAT;
bind[1].buffer= (char *)&price;
bind[1].is_null= 0;
bind[1].length= 0;

bind[2].buffer_type= MySQL_TYPE_LONG;
bind[2].buffer= (char *)&product_id;
bind[2].is_null= 0;
bind[2].length= 0;

// bind parameters
if (mysql_stmt_bind_param(stmt, bind))
```

```

{
    printf("mysql_stmt_bind_param() failed\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

// set updated values
// change these values!!
sprintf(name,"product-updated");
str_length = strlen(name);
price = 10.33;
product_id = 5;

printf("updating data...\r\n");
if (mysql_stmt_execute(stmt))
{
    printf("mysql_stmt_execute(), 1 failed\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}
printf("done.\r\n");
printf("closing connection...\r\n");

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    printf("failed while closing the statement\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}
mysql_close(con);
printf("closed.\r\n");

exit(0);
}

```

Save this code.

Now you can compile and run this file.

```

## 9.4.4 Deleting Data

The last operation is to delete data, for instance, delete data with id=3. Create a file, called **demo-delete-data.c** and write this code.

```

#include <my_global.h>
#include <mysql.h>
#include <string.h>

#define DELETE_DATA "delete from product where idproduct=?"

int main(int argc, char **argv)
{
    MYSQL *con = mysql_init(NULL);
```

```
if (con == NULL)
{
    fprintf(stderr, "%s\n", mysql_error(con));
    exit(1);
}
printf("connecting to mysql server...\r\n");
// change host, username, and password
if (mysql_real_connect(con, "localhost", "root", "password",
                       "mydatabase", 0, NULL, 0) == NULL)
{
    printf("error: %s\r\n", mysql_error(con));
    mysql_close(con);
    exit(1);
}
printf("connected.\r\n");

MYSQL_STMT *stmt;

stmt = mysql_stmt_init(con);
if (!stmt)
{
    printf(" mysql_stmt_init(), out of memory\r\n");
    exit(0);
}

if (mysql_stmt_prepare(stmt, DELETE_DATA, strlen(DELETE_DATA)))
{
    printf("mysql_stmt_prepare(), UPDATE failed\r\n");
    printf("error: %s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

int i;
MYSQL_BIND bind[1];
int product_id;

memset(bind, 0, sizeof(bind));

bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&product_id;
bind[0].is_null= 0;
bind[0].length= 0;

// bind parameters
if (mysql_stmt_bind_param(stmt, bind))
{
    printf("mysql_stmt_bind_param() failed\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}

// select product id to be deleted
```

```
// change these values!!
product_id = 3;

printf("deleting data...\r\n");
if (mysql_stmt_execute(stmt))
{
    printf("mysql_stmt_execute(), 1 failed\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}
printf("done.\r\n");
printf("closing connection...\r\n");

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    printf("failed while closing the statement\r\n");
    printf("%s\r\n", mysql_stmt_error(stmt));
    exit(0);
}
mysql_close(con);
printf("closed.\r\n");

exit(0);
}
```

Save this code.

Now you can compile and run this file.

```
$ gcc -c -I/usr/include/mysql demo-delete-data.c
$ gcc -o demo-delete-data demo-delete-data.o -L/usr/lib/mysql -lmysqlcli

## **10. Socket Programming**

This chapter explains how to get started with Socket programming using C.

## 10.1 Getting Local Hostname

We usually know our hostname using command hostname. For instance, you can type the following command.

```
$ hostname
```

We also can get our hostname by program. We can use gethostname() function. It is defined as below.

```
#include <unistd.h>

int gethostname(char *name, size_t len);
```

For illustration, we create a simple app to read local hostname. Create a file, called **gethostname.c**, and write this code.

```
#include <stdio.h>
#include <sys/unistd.h>

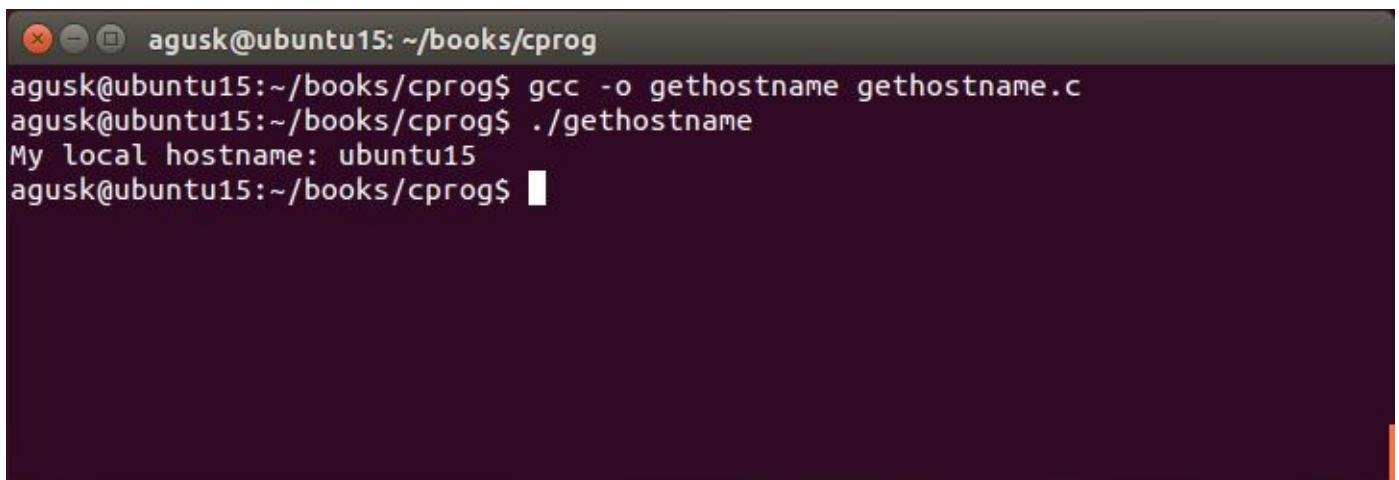

int main(void)
{
    char hostname[128];

    gethostname(hostname, sizeof(hostname));
    printf("My local hostname: %s\n", hostname);

    return 0;
}
```

Save this code and try to compile and run.

The following is a sample output.

A screenshot of a terminal window titled "agusk@ubuntu15: ~/books/cprog". The window shows the following command-line session:

```
agusk@ubuntu15:~/books/cprog$ gcc -o gethostname gethostname.c
agusk@ubuntu15:~/books/cprog$ ./gethostname
My local hostname: ubuntu15
agusk@ubuntu15:~/books/cprog$
```

## 10.2 Creating and Connecting

In this section we explore socket programming. For illustration we build client-server app. In this scenario, we just connect and then close.

To create communication, we can use `socket()` function. It can be defined as below.

```
#include <sys/types.h>
#include <sys/socket.h>

int socket(int domain, int type, int protocol);
```

domain is defined as below.

Name	Purpose
-----	
AF_UNIX, AF_LOCAL	Local communication
AF_INET	IPv4 Internet protocols
AF_INET6	IPv6 Internet protocols
AF_IPX	IPX - Novell protocols
AF_NETLINK	Kernel user interface device
AF_X25	ITU-T X.25 / ISO-8208 protocol
AF_AX25	Amateur radio AX.25 protocol
AF_ATMPVC	Access to raw ATM PVCs
AF_APPLETALK	Appletalk
AF_PACKET	Low level packet interface

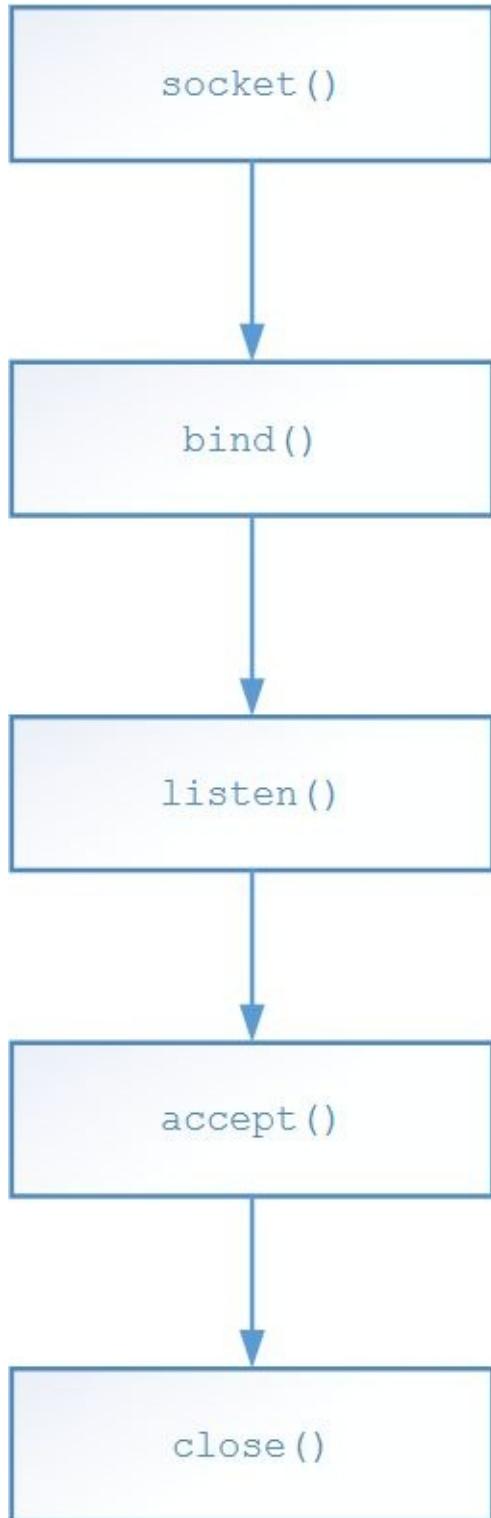

type is defined as below.

SOCK_STREAM	Provides sequenced, reliable, two-way, connection-based byte streams. An out-of-band data transmission mechanism may be supported.
SOCK_DGRAM	Supports datagrams (connectionless, unreliable messages of a fixed maximum length).
SOCK_SEQPACKET	Provides a sequenced, reliable, two-way connection-based data transmission path <b>for</b> datagrams of fixed maximum length; a consumer is required to <b>read</b> an entire packet with each input system call.
SOCK_RAW	Provides raw network protocol access.
SOCK_RDM	Provides a reliable datagram layer that does not guarantee ordering.
SOCK_PACKET	Obsolete and should not be used in new programs;

We will focus on socket type: `SOCK_STREAM` and `SOCK_DGRAM`.

## 10.2.1 Server

To build server, you can follow steps, shown in Figure below.

bind(), listen(), accept() and close() function can be defines as follows.

```
#include <sys/types.h>
#include <sys/socket.h>
```

```
#include <unistd.h>

int bind(int sockfd, const struct sockaddr *addr, socklen_t addrlen);
int listen(int sockfd, int backlog);
int accept(int sockfd, struct sockaddr *addr, socklen_t *addrlen);
int close(int fd);
```

We usually struct sockaddr\_in to pass parameter addr. It is defined as follows.

```
struct sockaddr_in {
    sa_family_t    sin_family; /* address family: AF_INET */
    in_port_t      sin_port;   /* port in network byte order */
    struct in_addr sin_addr;  /* internet address */
};

struct in_addr {
    uint32_t        s_addr;    /* address in network byte order */
};
```

For implementation, we build server app by creating a file, called **simple\_server.c**, and write this code.

```
1 #include <stdio.h>
2 #include <sys/types.h>
3 #include <sys/socket.h>
4 #include <netinet/in.h>
5 #include <string.h>
6 #include <errno.h>
7
8
9 int main(void)
10 {
11
12     int sockfd, newsockfd, portno, clilen;
13     struct sockaddr_in serv_addr, cli_addr;
14
15     portno = 8056; // server port
16     errno = 0;
17
18     sockfd = socket(AF_INET, SOCK_STREAM, 0);
19     if (sockfd < 0)
20     {
21         printf("\n socket() failed with error [%s]\n", strerror(errno));
22         return -1;
23     }
24
25     bzero((char *) &serv_addr, sizeof(serv_addr));
26
27     serv_addr.sin_family = AF_INET;
28     serv_addr.sin_addr.s_addr = INADDR_ANY;
29     serv_addr.sin_port = htons(portno);
```

```

30
31     if (bind(sockfd, (struct sockaddr *) &serv_addr,
32               sizeof(serv_addr)) < 0)
33     {
34         printf("\n bind() failed with error [%s]\n", strerror(errno));
35         return -1;
36     }
37
38     printf("socket has created and binded\n");
39     printf("listening incoming socket client...\n");
40
41     listen(sockfd, 5);
42     clilen = sizeof(cli_addr);
43     newsockfd = accept(sockfd, (struct sockaddr *) &cli_addr, &clilen);
44     if (newsockfd < 0)
45     {
46         printf("\n accept() failed with error [%s]\n", strerror(errno));
47         return -1;
48     }
49
50     printf("a client was connected\n");
51
52     // close socket
53     close(newsockfd);
54     close(sockfd);
55
56     return 0;
57 }
```

You can compile this program.

```
$ gcc -o simple_server simple_server.c
```

## 10.2.2 Client

To connect the server, we can use `connect()` function. This function can be defined as below.

```
#include <sys/types.h>
#include <sys/socket.h>

int connect(int sockfd, const struct sockaddr *addr,
            socklen_t addrlen);
```

Server information is passed to `addr` parameter.

For client implementation, we create a file, called **simple\_client.c**, and write this code.

```
1 #include <stdio.h>
2 #include <sys/types.h>
3 #include <sys/socket.h>
4 #include <netinet/in.h>
5 #include <netdb.h>
6 #include <string.h>
7 #include <errno.h>
8
9
10 int main(void)
11 {
12     int sockfd, portno;
13
14     struct sockaddr_in serv_addr;
15     struct hostent *server;
16
17     // server hostname. You can change it
18     char server_hostname[] = "ubuntu15";
19     portno = 8056; // server port
20     errno = 0;
21
22     sockfd = socket(AF_INET, SOCK_STREAM, 0);
23     if (sockfd < 0)
24     {
25         printf("\n socket() failed with error [%s]\n", strerror(errno));
26         return -1;
27     }
28
29     printf("socket has created\n");
30
31     server = gethostbyname(server_hostname);
32     if (server == NULL)
33     {
34         printf("\n gethostbyname() failed with error [%s]\n", strerror(errno));
35         return -1;
36     }
37
38     bzero((char *) &serv_addr, sizeof(serv_addr));
39     serv_addr.sin_family = AF_INET;
40     bcopy((char *)server->h_addr,
41           (char *)&serv_addr.sin_addr.s_addr,
42           server->h_length);
43     serv_addr.sin_port = htons(portno);
44
45     printf("connecting to server....\n");
46     if (connect(sockfd,(struct sockaddr *)&serv_addr,sizeof(serv_addr))
47     {
48         printf("\n connect() failed with error [%s]\n", strerror(errno));
49         return -1;
50     }
51
52     printf("connected to server\n");
53
```

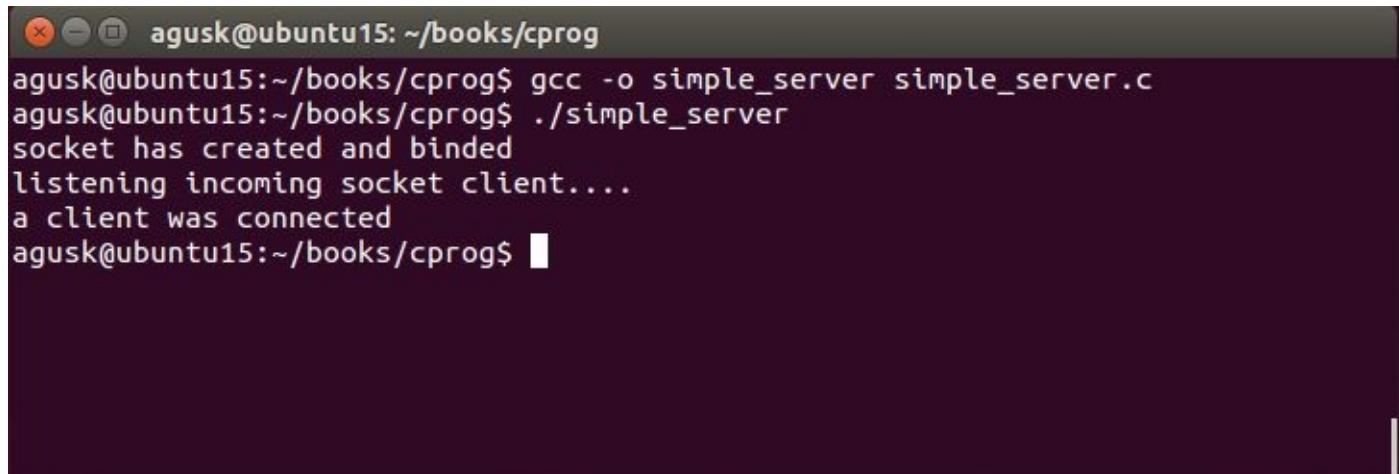

```
54     // close socket
55     close(sockfd);
56
57     return 0;
58 }
```

Save all code. Try to compile.

```
$ gcc -o simple_client simple_client.c
```

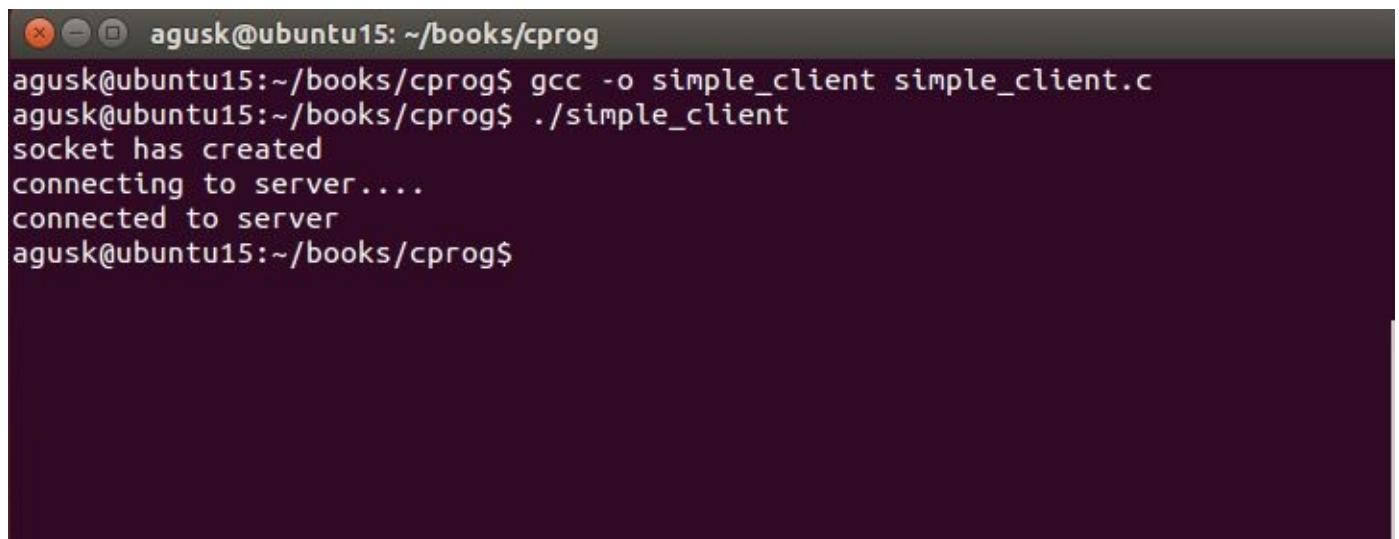

### 10.2.3 Testing

Now we can test our server and client app. Firstly we run server app. The following is a sample output.

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -o simple_server simple_server.c
agusk@ubuntu15:~/books/cprog$ ./simple_server
socket has created and binded
listening incoming socket client....
a client was connected
agusk@ubuntu15:~/books/cprog$
```

Then you run client app.

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -o simple_client simple_client.c
agusk@ubuntu15:~/books/cprog$ ./simple_client
socket has created
connecting to server....
connected to server
agusk@ubuntu15:~/books/cprog$
```

After client connected to server, server and client close connection.

## 10.3 Data Transfer

We can send and receive data via socket using read() and write functions. These functions are defined as below.

```
#include <unistd.h>

ssize_t read(int fd, void *buf, size_t count);
ssize_t write(int fd, const void *buf, size_t count);
```

These functions are general I/O functions. We can use specific I/O for socket operations using send() and recv() functions. They can implemented as follows.

```
#include <sys/types.h>
#include <sys/socket.h>

ssize_t send(int sockfd, const void *buf, size_t len, int flags);
ssize_t recv(int sockfd, void *buf, size_t len, int flags);
```

In this section we build client-server like section 10.2 but we try to transfer data using write() and read() functions.

### 10.3.1 Server

After client connected, we read data from client using read() function. Then we send message to client using write() function. After that, we close connection.

For implementation, we create a file, called **data\_server.c**, and write this code.

```
1 #include <stdio.h>
2 #include <sys/types.h>
3 #include <sys/socket.h>
4 #include <netinet/in.h>
5 #include <string.h>
6 #include <errno.h>
7
8
9 int main(void)
10 {
11
12     int sockfd, newsockfd, portno, clilen, sz;
13     char buffer[256];
14     struct sockaddr_in serv_addr, cli_addr;
15
16     portno = 8059; // server port
17     errno = 0;
```

```
18     sockfd = socket(AF_INET, SOCK_STREAM, 0);
19     if (sockfd < 0)
20     {
21         printf("\n socket() failed with error [%s]\n", strerror(errno))
22         return -1;
23     }
24
25     bzero((char *) &serv_addr, sizeof(serv_addr));
26
27     serv_addr.sin_family = AF_INET;
28     serv_addr.sin_addr.s_addr = INADDR_ANY;
29     serv_addr.sin_port = htons(portno);
30
31     if (bind(sockfd, (struct sockaddr *) &serv_addr,
32               sizeof(serv_addr)) < 0)
33     {
34         printf("\n bind() failed with error [%s]\n", strerror(errno));
35         return -1;
36     }
37
38     printf("socket has created and binded\n");
39     printf("listening incoming socket client...\n");
40
41     listen(sockfd, 5);
42     clilen = sizeof(cli_addr);
43     newsockfd = accept(sockfd, (struct sockaddr *) &cli_addr, &clilen);
44     if (newsockfd < 0)
45     {
46         printf("\n accept() failed with error [%s]\n", strerror(errno));
47         return -1;
48     }
49
50     printf("a client was connected\n");
51
52     // read data
53     sz = read(newsockfd, buffer, 255);
54     if (sz < 0)
55     {
56         printf("\n read() failed with error [%s]\n", strerror(errno));
57         return -1;
58     }
59     printf("Received message: %s\n", buffer);
60
61     // write data
62     sz = write(newsockfd, "this is message from server", 30);
63     if (sz < 0)
64     {
65         printf("\n write() failed with error [%s]\n", strerror(errno));
66         return -1;
67     }
68
69     // close socket
```

```
71     close(newsockfd);
72     close(sockfd);
73
74     return 0;
75 }
```

This code is similar to code on section 10.2.1 but we continue to read and send data.

Save this code and compile it.

```
$ gcc -o data_server data_server.c
```

## 10.3.2 Client

On client side, we send message after connected. Then we read message from server.

Let's start to create a file, called **data\_client.c**, and write this code.

```
1 #include <stdio.h>
2 #include <sys/types.h>
3 #include <sys/socket.h>
4 #include <netinet/in.h>
5 #include <netdb.h>
6 #include <string.h>
7 #include <errno.h>
8
9
10 int main(void)
11 {
12     int sockfd, portno, sz;
13
14     struct sockaddr_in serv_addr;
15     struct hostent *server;
16     char buffer[256];
17
18     // server hostname. You can change it
19     char server_hostname[] = "ubuntu15";
20     portno = 8059; // server port
21     errno = 0;
22
23     sockfd = socket(AF_INET, SOCK_STREAM, 0);
24     if (sockfd < 0)
25     {
26         printf("\n socket() failed with error [%s]\n", strerror(errno));
27         return -1;
28     }
29
30     printf("socket has created\n");
31 }
```

```

32     server = gethostbyname(server_hostname);
33     if (server == NULL)
34     {
35         printf("\n gethostbyname() failed with error [%s]\n", strerror(errno));
36         return -1;
37     }
38
39     bzero((char *) &serv_addr, sizeof(serv_addr));
40     serv_addr.sin_family = AF_INET;
41     bcopy((char *)server->h_addr,
42           (char *)&serv_addr.sin_addr.s_addr,
43           server->h_length);
44     serv_addr.sin_port = htons(portno);
45
46     printf("connecting to server...\n");
47     if (connect(sockfd,(struct sockaddr *)&serv_addr,sizeof(serv_addr)) < 0)
48     {
49         printf("\n connect() failed with error [%s]\n", strerror(errno));
50         return -1;
51     }
52
53     printf("connected to server\n");
54
55     // write data
56     strcpy(buffer,"this is message from client");
57     sz = write(sockfd,buffer,strlen(buffer));
58     if (sz < 0)
59     {
60         printf("\n write() failed with error [%s]\n", strerror(errno));
61         return -1;
62     }
63
64     // read data
65     bzero(buffer,256);
66     sz = read(sockfd,buffer,255);
67     if (sz < 0)
68     {
69         printf("\n read() failed with error [%s]\n", strerror(errno));
70         return -1;
71     }
72     printf("Received message: %s\n",buffer);
73
74     // close socket
75     close(sockfd);
76
77     return 0;
78 }
```

Save this code and compile it.

```
$ gcc -o data_client data_client.c
```

### 10.3.3 Testing

We are ready to test our client-server app. Firstly we run server app.

The following is a sample output for server app.

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -o data_server data_server.c
agusk@ubuntu15:~/books/cprog$ ./data_server
socket has created and binded
listening incoming socket client....
a client was connected
Received message: this is message from client|00|
agusk@ubuntu15:~/books/cprog$
```

Then we run client app. You can see the output, shown in Figure below.

```
agusk@ubuntu15:~/books/cprog
agusk@ubuntu15:~/books/cprog$ gcc -o data_client data_client.c
agusk@ubuntu15:~/books/cprog$ ./data_client
socket has created
connecting to server....
connected to server
Received message: this is message from server
agusk@ubuntu15:~/books/cprog$
```
